Exploration of New Reactivities of Azetidinols and Alkynylborates

Yasuhiro Shimamoto

2014

Preface

The studies presented in this thesis have been carried out under the direction of Professor Masahiro Murakami at Kyoto University during 2008-2014. The studies concerned with the development of the new synthetic reactions using azetidinols and alkynyl borates.

The author would like to express his sincerest gratitude to Professor Masahiro Murakami for his kind guidance, powerful encouragement, stimulating discussions throughout this study. The author learned a lot of things from Professor Murakami. They are not only chemistry but also important things to live.

The author is grateful to Assistant Professor Naoki Ishida for his support and teaching chemical techniques and discussions. The author is also grateful to Associate Professor Tomoya Miura, and Assistant Professor Akira Yada for their discussion and suggestion.

The author was fortunate to have had a lot of assistance of Dr. David Neças, Ms. Hanako Sunaba, and Mr. Takaaki Yano. The author acknowledge to them for their patience, earnest, and collaborations.

The author wishes to express his gratitude to Dr. Peter Brüchner, Dr. Akiko Okamoto, Dr. Lantao Liu, Dr. Changkun Li, Dr. Scott G. Stewart, Dr. Hiroshi Shimizu, Dr. Masanori Shigeno, Dr. Motoshi Yamauchi, Dr. Takeharu Toyoshima, Mr. Yoshiteru Ito, Ms. Mizuna Narumi, Mr. Yoshiyuki Yamaguchi, Mr. Keita Ueda, Mr. Taisaku Moriya, Mr. Tomohiro Igarashi, Mr. Masao Morimoto, Mr. Taiga Yamamoto, Mr. Osamu Kozawa, Ms. Paula de Mendoza Bonmati, Mr. Shota Sawano, Mr. Wataru Ikemoto, Mr. Yusuke Mikano, Mr. Akira Kosaka, Mr. Tsuneaki Biyajima, Mr. Yuuta Nakanishi, Mr. Tatsuya Yuhki, Mr. Kentaro Hiraga. Ms. Yui Nishida, Mr. Yusuke Masuda, Mr. Takamasa Tanaka, Mr. Yuuta Funakoshi, Mr. Tetsuji Fujii, Mr. Shintaro Okumura, Mr. Shoichiro Fujita, Mr. Yuuki Yamanaka, Mr. Takayuki Nakamuro, Mr. Andreas Fetzer, Mr. Norikazu Ishikawa, Mr. Shoki Nishi, Mr. Kohei Matsumoto, Ms. Yuki Sakai, and all other members of Murakami Laboratory for their enthusiasm and kind consideration.

The author is grateful to Mr. Daishi Fujino, Mr. Kenichiro Nakai, Mr. Momotaro Takeda, Mr. Yosuke Tani, and all other friends for stimulating conversation with them.

The author thanks Mr. Haruo Fujita, Mr. Tadashi Yamaoka, Ms. Keiko Kuwata, Ms.

Midori Yamamura, Ms. Sakiko Goto, Ms. Eriko Kusaka, Ms. Karin Nishimura for the measurement of NMR spectra and Mass spectra.

The author is grateful for Research Fellowships of the Japan Society for the Promotion of Science for Young Scientists.

Finally, the author expresses his deep appreciation to his family, especially his parents, Mr. Takashi Shimamoto, Ms. Akiyo Shimamoto for their constant assistant and encouragement.

General Introduction

Organic synthesis has contributed to our lives. For example, various chemical industries, pharmaceutical chemistry, material chemistry, and others make our lives more comfortable and convenient.

In this thesis, the author would like to describe new synthetic reactions which are directed towards following issues.

- (1) Solar-driven incorporation of carbon dioxides into α -amino ketones
- (2) 1,5-Rhodium shift in rearrangement of *N*-arenesulfonylazetidins into benzo-sultams
- (3) Palladium catalyzed reaction of alkynylborates with aryl halides

(1) Solar-driven incorporation of carbon dioxides into α -amino ketones

The utilization of solar energy is an attractive subject in organic synthesis because solar energy is one of the most sustainable energy in the world.¹ On the other hand, the utilization of carbon dioxides as the C1 source is still significant challenge because of its stability.² In chapter 1, the author describes solar-driven incorporation of carbon dioxide into α -amino ketones. In first step, photoreaction promoted by solar light produces azetidins.³ This transformation is endergonic, thus harvesting the solar energy as the chemical energy in the form of structural strain. In second step, carbon dioxides is incorporated into the azetidins to afford cyclic carbonates. The relief of the structural strain serves as driving force for the CO₂ incorporation reaction. This two phase reaction system demonstrates a simple model of chemical utilization of solar energy for CO₂ incorporation.

(2) 1,5-Rhodium shift in rearrangement of *N*-arenesulfonylazetidins into benzosultams

1,n-metal shift is an attractive process which enables unique metal catalyzed reactions. Therefore, many reactions have been developed via a 1,n-metal shift. Especially, a lot of rhodium, and palladium catalyzed reactions involving 1,4-metal shift have been developed.^{4,5,6} However, there are much less examples of 1,5-metal shift than 1,4-metal shift.⁷

In chapter 2, the author describes rhodium catalyzed rearrangement of *N*-arenesulfonylazetidins into benzosultams via 1,5-rhodium shift. Various benzosultams were obtained in quantitative yield. In addition, chiral azetidins, which are easily available by modified Seebach's procedure⁸, afford the enatio- and diastereopure benzosultams quantitatively.

(3) Palladium catalyzed reaction of alkynylborates with aryl halide

Organoboron compounds are versatile synthetic reagents for carbon-carbon bond formation reactions, because they are easily handled and have the well known reactivities⁹. In addition, their utilizations are increasing in the field of pharmaceutical chemistry¹⁰, and material science¹¹. Therefore, it is the important for organic chemists to develop the new efficient methods to synthesis the organoboron compounds precisely.

Alkynylborates react with electrophiles on the β -position of boron to afford the alkenylboranes which are difficult to synthesize by other conventional methods¹². We have focused such reactivities and developed a palladium catalyzed reaction of alkynylborates¹³.

In chapter 3, the author describes the palladium catalyzed reaction of alkynylborates with aryl halides, which provides the trisubstituted alkenylboranes regio- and stereoselectively. The stereochemistry of the alkenylboranes is dependent upon the ligand employed. Using Xantphos as the ligand, (*Z*)-alkenylboranes were obtained stereoselectively. On the other hand, in the case of (*o*-tol)₃P, (*E*)-alkenylboranes were obtained.

Oligo(arylenevinylene)s are important compounds in the field of material science¹⁴. Though a wide variety of oligo(arylenevinylene)s have been synthesized, oligo(arylenevinylene)s with tetrasubstituted olefin units have not been synthesized. In chapter 4, the author describes an iterative approach to this class of molecules. Various oligo(arylenevinylene)s are synthesized stereoselectively starting from bromo (iodo) benzenes and alkynylborates.

Indene skeleton is an important substructure in the field of pharmaceutical chemistry and material science. An annulation reaction of *o*-halobenzoyl compounds with alkyne provides an efficient way to synthesize indenols, however, it is difficult to control the regioselectivity. In chapter 5, the author describes a palladium-catalyzed reaction of

alkynylborates with *o*-iodophenyl ketones, which provides 2,3-disubstituted indenols regioselectively.

Chapter 1

Solar-Driven Incorporation of Carbon Dioxide into α -Amino Ketones

Abstract

α -Amino ketones react with carbon dioxides to give cyclic carbonates via photocyclization promoted by solar light. This reaction demonstrates a model of chemical utilization of solar energy for CO₂ incorporation.

Introduction

The recent manifestation of the potential risk inherent to nuclear technologies has incited a strong demand for exploration of innovative means to exploit energy from natural sources, thus increasing the need for research on sustainable energy in many scientific fields. Chemists can contribute by developing chemical systems to utilize solar light, which is undoubtedly the best source of sustainable energy available on the planet.¹ Another imperative issue is the establishment of carbon-neutral systems.² One synthetic approach to this issue is the incorporation of CO₂ into organic compounds as a chemical feedstock.³ High-energy compounds suit energetically low CO₂ as the reaction partner. Under these circumstances, it presents a significant challenge to simultaneously tackle the two issues mentioned above. Thus, we tried to develop a reaction that is promoted by solar light and utilizes CO₂ as a chemical feedstock (Figure 1).

Figure 1. Solar Driven Incorporation of Carbon Dioxide

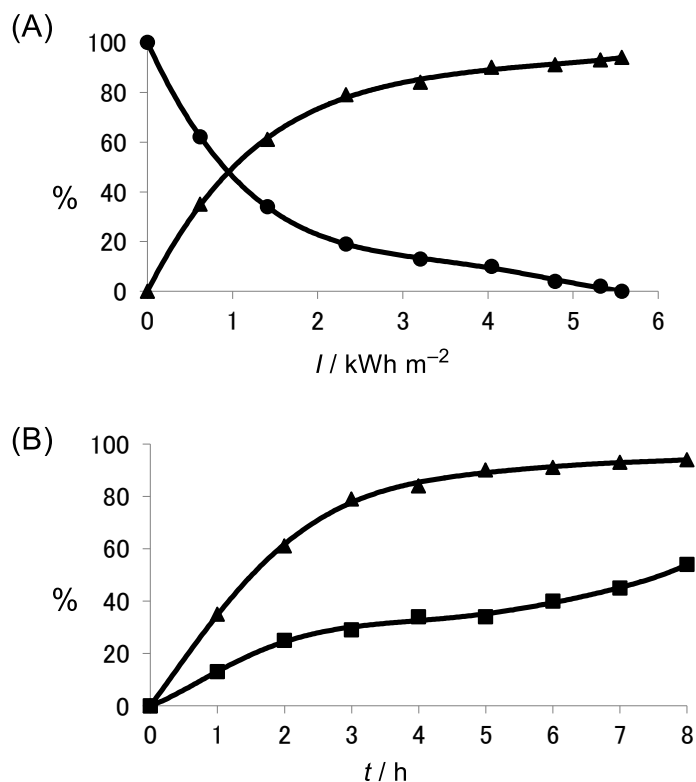

Results and Discussion

We report herein a solar-driven process that incorporates CO₂ into α -methylamino ketones. The resulting aminosubstituted cyclic carbonates are expected to be useful building blocks of pharmaceuticals and fuel additives.⁴ Our attention was initially directed to a photochemical cyclization reaction observed with α -methylamino ketones.⁵ Of note was that this photoreaction proceeded in an energetically uphill direction. A high-energy four-membered ring⁶ was constructed through the insertion of a photo-excited carbonyl group into the carbon-hydrogen bond of a pendant methyl group on a nitrogen atom. In a formal sense, the intrinsically inert carbon-hydrogen bond was cleaved⁷ and added across the carbon-oxygen double bond in a 4-exo-trig mode.⁸ Although the reaction was originally reported to require irradiation with a mercury lamp, which used electricity,^{5b} we discovered that natural solar light successfully effected this energetically uphill reaction; α -amino ketone **1a** cyclized at a reasonable rate upon exposure to solar light (Scheme 1).

Scheme 1. Solar Light Promoted Cyclization of **1a**

Furthermore, ordinary Pyrex glass, not quartz was suitable for the reaction vessel; light of wavelengths below 400 nm was required for the photoreaction, and Pyrex glass transmitted a sufficient amount of operative light even on a cloudy day. Thus, simply setting a Pyrex tube containing a solution of **1a** in *N,N*-dimethylacetamide (DMA) on a balcony or rooftop brought about the cyclization. The conversion was dependent upon the amount of solar radiation. We defined it as “sunny” when an hourly solar radiation over 0.4 kWm^{-2} was observed, and as “cloudy” when it ranged from 0.1 to 0.4 kWm^{-2} . Typically, the total amount of solar radiation amounted to 5.5 kWhm^{-2} in eight hours on a sunny day to cause full conversion of **1a** on a 0.1 mmol scale (0.10 mmolL^{-1} ; Figure 2A). The reaction mixture was subsequently applied to conventional column chromatography on silica gel and analytically pure azetidinol **2a** was isolated in 91% yield. In contrast, an analogous experiment on a cloudy day produced **2a** in 54% yield after eight hours (Figure 2B), when the total amount of solar radiation reached 0.9 kWhm^{-2} . Thus, it turned out to be possible to transfer **1a** into the product⁹ by using solar energy even on a cloudy day.

Figure 2. Solar-Light Promoted Cyclization of 1a

(A) Residual ratio of **1a** (●) and yield of **2a** (▲) during solar radiation, (B) Yield of **2a** over time on sunny (▲) and cloudy day (■)

We next attempted to incorporate CO_2 into azetidinol **2a**, in which energy has been stored, by reacting it with CO_2 , and a remarkably simple way was found; CO_2 was successfully incorporated upon exposure of a solution of **2a** in DMA to gaseous CO_2 in the presence of a base. For example, stirring a heterogeneous mixture of **2a** and Cs_2CO_3 (4.0 equiv) in DMA under an atmosphere of CO_2 (1 atm) at 60°C for ten hours led to the quantitative production of the cyclic carbonate **3a**, which was isolated in 93% yield after purification by chromatography (Scheme 2). Organic bases, such as 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU), also afforded **3a**, albeit in a lower yield (56%).

Scheme 2. Incorporation of Carbon Dioxide

The formation of **3a** is explained by assuming the pathway depicted in Scheme 3.⁴ Azetidinol **2a** is initially deprotonated by Cs_2CO_3 to produce alkoxide anion **A**, which subsequently adds to CO_2 to afford carbonate anion **B**. The following nucleophilic attack of the anionic oxygen onto the 2-carbon atom prompts displacement of the tosylamide anion through a 5-exo-tet process.⁸ Thus, the four-membered ring is opened, thereby releasing the energy originating from sun. Finally, protonation of **C** affords **3a**.

Scheme 3. Plausible Mechanism

For comparison, pyrrolidinol **4** was subjected to the identical reaction conditions. Unlike the four-membered counterpart **2a**, the five-membered compound **4** failed to react and was recovered unchanged. The contrasting results observed with **2a** and **4** lend support to the explanation that the major driving force for the CO_2 -capturing reaction is the release of the energy stored in the form of the strained four-membered ring.

The experimental procedures for both the photochemical cyclization reaction and the CO_2 -capturing reaction are so simple that it is possible to carry them out in a single flask (Scheme 4). Initially, a DMA solution of **1a** in an atmosphere of CO_2 (1 atm) was irradiated with solar light outside. After completion of the photoreaction, Cs_2CO_3 was simply added to the reaction mixture, which was then heated at 60°C for ten hours in a

fume hood. Isolation by chromatography afforded the analytically pure cyclic carbonate **3a** in 83% yield based on **1a**.

Scheme 4. Solar Driven Incorporation of Carbon Dioxide into α -Amino Ketone **1a**

The broad generality of this consecutive process was verified by application to various acetophenone derivatives (Scheme 5). Both an electron-donating methoxy group and an electron-withdrawing trifluoromethyl group were allowed at the para-position of the benzoyl group, and the corresponding products **3b** and **3c** were isolated in reasonable total yields. The presence of possibly photoactive bromo and chloro groups¹⁰ had essentially no effect on the reaction (**3d** and **3e**). Sulfonyl groups other than a p-toluenesulfonyl group were also suitable as the substituent on the nitrogen atom (**3f-h**).

Table 1. Scope of Solar Driven CO₂ Incorporation into α -Amino Ketone

Overall yields of isolated products are given. Reactions were conducted on a 0.2 mmol scale with the following reagents and conditions: **1** (0.20 mmol), DMA (1.0 mL), solar light, ambient temperature, CO₂ (1 atm); then Cs₂CO₃ (0.80 mmol), 60 °C.

Conclusions

In summary, we have developed the unique solar-driven transformation of α -amino ketones. CO_2 is incorporated to afford amino-substituted cyclic carbonates, which are potentially useful ingredients in industry.

Although photosynthesis is a complex assembly of a number of elementary reactions, it can be divided into two major reactions; the light reaction and the dark reaction. In the former reaction, solar energy is captured to promote an energetically uphill process with production of high-energy molecules (adenosine triphosphate (ATP) and nicotinamide adenine dinucleotide phosphate (NADPH)). The dark reaction is an energetically downhill process that does not require light. ATP and NADPH, which have chemically stored solar energy during the former reaction, assist in the fixation of CO_2 , which is intrinsically low in energy. Photosynthesis as a whole reduces CO_2 into carbohydrates. Although the present consecutive process does not involve CO_2 reduction, its mechanistic profile of energy resembles that of photosynthesis and presents a simple model of the chemical utilization of solar energy for CO_2 incorporation.

Experimental Section

General. All reactions were carried out with standard Schlenk techniques. IR measurements were performed on a FTIR SHIMADZU DR-8000 spectrometer fitted with a Pike Technologies MIRacle Single Reflection ATR adapter. ^1H and ^{13}C NMR spectra were recorded on a Varian Mercury-vx400 (^1H at 400.44 MHz and ^{13}C at 100.69 MHz) spectrometer. NMR data were obtained in CDCl_3 . Proton chemical shifts were referenced to the residual proton signal of CHCl_3 at 7.26 ppm. Carbon chemical shifts were referenced to the carbon signal of CDCl_3 at 77.0 ppm. High-resolution mass spectra were recorded on a Thermo Scientific Exactive (ESI) spectrometer. Flash column chromatography was performed with silica gel 60N (Kanto). Preparative thin-layer chromatography (PTLC) was performed on silica gel plates with PF254 indicator (Merck).

Materials. Unless otherwise noted, all chemicals and anhydrous solvents were obtained from commercial suppliers. (2-Pyridyl)sulfonyl chloride¹ was prepared according to the reported procedure.

Preparation of α -Amino Ketone 1a: A Typical Procedure for the Preparation of α -Amino Ketone 1a-1h

To an Et_2O solution (40 mL) of *p*-toluenesulfonyl chloride (3.8 g, 20 mmol) was added an aqueous solution of methylamine (40 wt%, 4.0 mL). After being stirred for 6 h at room temperature, water was added to the reaction mixture. The organic layer was separated and the remaining aqueous layer was extracted with AcOEt (3 times). The combined organic layer was washed with brine (once), dried over MgSO_4 and concentrated. The residue was subsequently dissolved in acetonitrile. 2-Bromoacetophenone (4.0 g, 20 mmol) and potassium carbonate (2.8 g, 20 mmol) were added therein. After being stirred overnight, water was added to the reaction mixture. The aqueous layer was extracted with AcOEt (3 times), washed with brine (once), dried over MgSO_4 and concentrated. The residue was purified by Flash column chromatography on silica gel (hexane/ethyl acetate = 5/1) to afford the α -amino ketone

1a (5.1 g, 17 mmol, 84% yield).

^1H NMR: δ = 2.44 (s, 3H), 2.83 (s, 3H), 4.57 (s, 2H), 7.33 (dd, J = 8.8, 0.4 Hz, 2H), 7.45-7.51 (m, 2H), 7.60 (tt, J = 7.6, 1.2 Hz, 1H), 7.71-7.75 (m, 2H), 7.95-7.99 (m, 2H); ^{13}C NMR: δ = 21.5, 35.6, 56.0, 127.5, 128.2, 128.8, 129.7, 133.8, 134.7, 134.8, 143.6, 193.7; HRMS (ESI $^+$): Calcd for $\text{C}_{16}\text{H}_{18}\text{NO}_3\text{S}$, $\text{M}+\text{H}^+$ 304.1002, Found m/z 304.0994; IR (ATR): 1693, 1339, 1227, 1157, 743 cm^{-1} .

Photoreaction of α -Amino Ketone **1a** upon Irradiation with Solar Light

α -Amino ketone **1a** (30.3 mg, 0.10 mmol) was placed in a Pyrex flask, which was subsequently filled with an atmospheric pressure of CO_2 by vacuum-refill cycles. The flask was added *N,N*-dimethylacetamide (1.0 mL) and exposed to solar light outside. After 10 h, water was added to the reaction mixture, and the aqueous layer was extracted with Et_2O (3 times), washed with water (3 times), brine (once), dried over MgSO_4 and concentrated. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 2/1) to afford the azetidinol **2a**.

(25.3 mg, 0.091 mmol, 91% yield).

^1H NMR: δ = 2.29 (s, 1H), 2.48 (s, 3H), 3.97 (d, J = 9.6 Hz, 2H), 4.15 (d, J = 9.6 Hz, 2H), 7.28-7.37 (m, 5H), 7.40 (d, J = 8.0 Hz, 2H), 7.79 (d, J = 8.0 Hz, 2H); ^{13}C NMR: δ = 21.6, 65.2, 70.3, 124.4, 128.1, 128.4, 128.6, 129.9, 131.2, 142.0, 144.4; HRMS (ESI $^+$): Calcd for $\text{C}_{16}\text{H}_{18}\text{NO}_3\text{S}$, $\text{M}+\text{H}^+$ 304.1002, Found m/z 304.0995. Found: C, 63.17; H, 5.55; N, 4.58; O, 15.55; S, 10.58; IR (ATR): 3477, 1333, 1184, 1148, 671 cm^{-1} .

Reaction of Azetidinol **2a** with Carbon Dioxide

Under an atmospheric pressure of CO_2 , an *N,N*-dimethylacetamide solution (1.0 mL) containing azetidinol **2a** (30.3 mg, 0.10 mmol) and cesium carbonate (130 mg, 0.40 mmol) were stirred at 60 $^\circ\text{C}$ for 10 h. The reaction mixture then treated with HCl aq (2.0 M), and the aqueous layer was extracted with Et_2O (3 times). The combined organic layer was washed with water (3 times), brine (once), dried over MgSO_4 and concentrated. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 3/1) to afford the cyclic carbonate **3a** (32.2 mg, 0.093 mmol, 93% yield).

One-Pot Reaction of α -Amino Ketone **1a with Carbon Dioxide.****A Typical Procedure for the CO₂-Capturing Reaction of α -Amino Ketones.**

α -Amino ketone **1a** (30.3 mg, 0.10 mmol) was placed in a Pyrex flask, which was subsequently filled with an atmospheric pressure of CO₂ by vacuum-refill cycles. The flask was added *N,N*-dimethylacetamide (1.0 mL) and exposed to solar light outside. After completion of the photochemical reaction, Cs₂CO₃ (130 mg, 0.40 mmol) was added to the reaction mixture, which was then stirred at 60 °C for 10 h in a room. The reaction mixture was treated with HCl aq. (2.0 M) and the aqueous layer was extracted with Et₂O (3 times). The combined organic layer was washed with water (3 times), brine (once), dried over MgSO₄ and concentrated. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 3/1) to afford the cyclic carbonate **3a** (28.8 mg, 0.083 mmol, 83% yield).

Synthesis of *N*-Tosyl-3-phenyl-3-pyrrolidinol **4** from *N*-Tosyl-3-pyrrolidinone

CeCl_3 (570 mg, 1.5 mmol) was dried under vacuum at 140 $^{\circ}\text{C}$ for 5 h. After cooling the flask to ambient temperature, the vessel was filled with argon. THF (5.0 mL) was added therein. The resulting suspension was cooled to -78 $^{\circ}\text{C}$ and PhLi (1.0 M in Et_2O , 1.5 mL, 1.5 mmol) was added. After being stirred for 30 min, *N*-tosyl-3-pyrrolidinone (240 mg, 1.0 mmol) was added. The cooling bath was removed to allow the mixture to reach

room temperature. The reaction was quenched by adding NH_4Cl aq. and the aqueous layer was extracted with AcOEt (3 times). The combined organic layer was washed with brine (once), dried over MgSO_4 and concentrated. The residue was purified by flash column chromatography on silica gel (hexane/ethyl acetate = 3/1) to afford the *N*-tosyl-3-phenyl-3-pyrrolidinol **4** (270 mg, 0.85 mmol, 85% yield)

^1H NMR: δ = 1.99 (br s, 1H), 2.09-2.15 (m, 1H), 2.18-2.27 (m, 1H), 2.43 (s, 3H), 3.51-3.64 (m, 4H), 7.26-7.38 (m, 7H), 7.73-7.77 (m, 2H); ^{13}C NMR: δ = 21.5, 39.6, 46.9, 60.8, 80.4, 125.0, 127.6, 128.0, 128.6, 129.7, 133.9, 141.8, 143.5; HRMS (ESI^+): Calcd for $\text{C}_{17}\text{H}_{23}\text{N}_2\text{O}_3\text{S}$, $\text{M}+\text{NH}_4^+$ 335.1424, Found m/z 335.1412; IR (ATR): 3491, 1325, 1159, 1101, 770 cm^{-1} .

Chapter 2

1,5-Rhodium Shift in Rearrangement of *N*-Arenesulfonylazetidin-3-ols into Benzosultams

Abstract

Benzosultams are synthesized in an enantiopure form starting from α -amino acids through a rhodium-catalyzed rearrangement reaction of *N*-arenesulfonylazetidin-3-ols. Mechanistically, it involves C-C bond cleavage by β -carbon elimination and C-H bond cleavage by 1,5-rhodium shift.

Introduction

Carbon–carbon (C–C) and carbon–hydrogen (C–H) bonds constitute the major frameworks of organic molecules. Such nonpolar σ -bonds are kinetically inert and thermodynamically stable in general, and therefore, remain intact under most conventional reaction conditions. The past few decades, however, have seen the rise of methods to selectively transform such intrinsically unreactive bonds with the use of transition metal catalysts.^{1,2}

A 1,4-metal shift is defined as an intramolecular metal-hydrogen exchange process occurring between 1- and 4-positions. This process provides a convenient way to activate a specific C–H bond, and a number of unique reactions involving a 1,4-metal shift have been reported.^{3–6} For example, Catellani and coworkers have reported a palladium-catalyzed reaction of bromobenzenes with norbornenes, in which multiple C–C bonds are introduced on the benzene ring through a 1,4-palladium shift.^{4a} A 1,4-rhodium shift has been also successfully exploited.⁵ Phenylboronic acid is multiply alkylated with norbornene through repetition of a 1,4-rhodium shift.^{5a} Indanones are synthesized through rearrangement of 1-arylpropargyl alcohols.^{5c,d} A rearrangement reaction of cyclobutanols affords indanols in an enantio- and diastereoselective way.^{5h,i} On the other hand, there are significantly less precedents reported for a 1,5-metal shift.⁷ Herein, we report a rearrangement reaction of *N*-arenesulfonylazetidin-3-ols into benzosultams⁸ which involves a 1,5-rhodium shift as the key mechanistic element. It provides a stereoselective synthetic pathway starting from natural α -amino acids leading to enantiopure benzosultams, which are substructures of potent pharmaceuticals like Piroxicam and Meloxicam.⁹

Results and Discussion

Initially, *N*-*p*-toluenesulfonylazetidinol **1a** was prepared from commercially available azetidin-3-ol in 3 steps.¹⁰ Then, the reaction of **1a** was examined in the presence of $[\text{Rh}(\text{OH})(\text{cod})]_2$ (2 mol %) and various phosphine ligands (Rh : P = 1 : 2.5).¹⁰ Whereas almost no reaction occurred when ligands like PPh_3 , DPPB, DPPF were employed, the use of *rac*-BINAP prompted a rearrangement reaction to give **2a** in 46% yield. *Rac*-DM-BINAP, which possessed 3,5-xylyl groups in place of phenyl groups on phosphorus, exhibited a considerably higher activity to promote quantitative transformation of **1a**. Simple elution of the reaction mixture through a pad of silica gel afforded **2a** in 96% isolated yield (Scheme 1).

Scheme 1. Rhodium-Catalyzed Rearrangement of **1a** to **2a**

A stepwise mechanism involving a 1,5-rhodium shift from $\text{C}(\text{sp}^3)$ to $\text{C}(\text{sp}^2)$ is proposed to explain the formation of **2a** from **1a** (Scheme 2). Initially, the hydroxy group of **1a** is exchanged onto the rhodium hydroxide to generate rhodium alkoxide **A**. Subsequently, β -carbon elimination follows to cleave the carbon–carbon bond of the symmetrical azetidine ring, thereby relieving the ring strain.¹¹ The generated alkylrhodium **B** then undergoes a 1,5-rhodium shift to furnish arylrhodium species **C**. An intramolecular 6-*exo* addition to the carbonyl group¹² occurs with **C** to reconstruct the six-membered ring structure of a benzosultam skeleton. Finally, the rhodium alkoxide **D** is exchanged with the hydroxy group of another azetidinol **1a** to release the benzosultam **2a** with regeneration of intermediate **A**.

Scheme 2. Proposed Mechanism for the Rearrangement of **1a** to **2a**

We next carried out the reaction of **1a-d**, whose *p*-tolyl group was fully deuterated (Scheme 3). One of the deuterium atoms on the ortho positions of the *p*-tolyl moiety was transferred onto the *N*-methyl group of **2a-d**, being consistent with the proposed

mechanism. The H/D ratio of the *N*-methyl group and the 8-position were 1.9/1.1 and 0.1/0.9, respectively. The slightly lower and higher H/D ratios at the *N*-methyl and 8-positions, respectively, than expected may suggest the microscopic reversibility between the intermediary arylrhodium **C** and the alkylrhodium **B**.

Scheme 3. Rhodium-Catalyzed Reaction of **1a-d** to **2a-d**

Next, optically active diphosphine ligands were examined to induce enantioselectivity at the step of intramolecular carbonyl addition, *i.e.* from **C** leading to **D**.¹² Although (*R*)-DM-BINAP exhibited the best reactivity among the chiral ligands examined to give **2a** in 94% yield, the enantiomeric ratio (er) was low (62:38). (*R*)-DIFLUORPHOS afforded the best selectivity of 92:8 er (91% yield).¹⁰ Application of this reaction conditions to various azetidins **1** furnished benzosultams **2** in the range of 91:9 to 93:7 er (Table 1).

Table 1. Enantioselective Rearrangement of **1 to **2**^{a,b}**

^a Reaction conditions: $[\text{Rh}(\text{OH})(\text{cod})]_2$ (5 mol %), (*R*)-DIFLUORPHOS (12 mol %), toluene, 60 °C, 12 h. ^b Isolated yield.

Asymmetrical azetidinol **1e** was prepared in an enantiopure form from (*L*)-alanine according to the modified Seebach's method (Scheme 4).¹³ Initially, (*L*)-alanine (**3**) was treated with *p*-toluenesulfonyl chloride to afford *N*-tosylate **4**. Subsequent treatment with oxalyl chloride followed by coupling with diazomethane gave diazo ketone **5**. Copper-catalyzed denitrogenative cyclization of **5** afforded azetidinone **6**. Addition of phenylmagnesium bromide to **6** occurred selectively from the face opposite to the methyl group to furnish azetidinol **1e** in an enantiopure form.

Scheme 4. Synthesis of Enantiopure Azetidinol **1e**

The azetidinol **1e** was heated at 60 °C in toluene for 8 h in the presence of $[\text{Rh}(\text{OH})(\text{cod})]_2$ (2 mol %) and *rac*-DM-BINAP (5 mol %) (Scheme 5). The rearrangement reaction proceeded efficiently to furnish the benzosultam **2e** in a quantitative yield stereoselectively with the enantiopurity retained. The stereochemistry was confirmed by X-ray crystallography.¹⁰

Scheme 5. Rearrangement of **1e** to **2e**

The exclusive formation of **2e** demonstrates that the β -carbon elimination occurs site-selectively at the methylene side rather than at the methyne side, probably due to

steric reasons. In addition, intramolecular carbonyl addition takes place in a diastereoselective fashion. We assume that the six-membered ring transition state takes a boat-like conformation, in which the C–Rh linkage can align with the C=O bond for the maximum orbital interaction as shown in Scheme 8. With the conformer **E**, the methyl group at the α -position takes a pseudoequatorial position, whereas the α -methyl group of the conformer **E'** takes a pseudoaxial position. Thus, the conformer **E** is favored over the conformer **E'** to produce the adduct **F** diastereoselectively.

Scheme 6. Models for Diastereoselective 6-*exo-dig* Cyclization

Various benzosultams were synthesized in an enantio- and diastereopure form (Table 2). The reaction of *N*-*p*-toluenesulfonylazetidinol **1f**, the diastereomer of **1e**, also furnished the same stereoisomer **2e** exclusively, being consistent with the proposed mechanism; the stereochemistry of the alcohol moiety once disappears upon β -carbon elimination to produce the same intermediate **C**. Azetidinols **1g-1j** having various aryl groups on the sulfonyl moiety gave the corresponding products **2g-2j** (entries 2-5). The reaction of *N*-*m*-toluenesulfonylazetidinol **1i** gave product **2i** with complete regioselectivity (entry 4), suggesting that rhodium preferred the sterically less hindered position as the destination of its 1,5-shift. Substituted aryl groups were allowed at the C3-position (entries 6, 7).¹⁴ Benzosultam **2m** was obtained from azetidinol **1m**, which was prepared from valine (entry 8). The reaction of methionine-derived **1n** successfully furnished **2n**, demonstrating the compatibility of a sulfide functionality (entry 9).

Conclusions

In summary, we have described the rhodium-catalyzed rearrangement reaction of *N*-arenesulfonylazetidins into benzosultams. The unique transformation mechanistically involves reorganization of nonpolar σ -bonds via 1,5-rhodium shift, and provides a method to synthesize enantio- and diastereopure benzosultams starting from natural α -amino acids.

Experimental Section

General. All reactions were carried out with standard Schlenk techniques. IR measurements were performed on a FTIR SHIMADZU DR-8000 spectrometer fitted with a Pike Technologies MIRacle Single Reflection ATR adapter. ^1H and ^{13}C NMR spectra were recorded on a Varian Mercury-vx400 (^1H at 400.44 MHz and ^{13}C at 100.69 MHz) and JEOL JNM-ECA600 (^1H at 600.17 MHz) spectrometer. NMR data were obtained in CDCl_3 and C_6D_6 . Proton chemical shifts were referenced to the residual proton signal of the solvent at 7.26 ppm (CHCl_3) and 7.16 ppm (C_6D_6). Carbon chemical shifts were referenced to the carbon signal of the solvent at 77.0 ppm (CDCl_3). High-resolution mass spectra were recorded on a Thermo Scientific Exactive (ESI) spectrometer. Flash column chromatography was performed with silica gel 60N (Kanto). Preparative thin-layer chromatography (PTLC) was performed on silica gel plates with PF254 indicator (Merck).

Materials. Unless otherwise noted, all chemicals and anhydrous solvents were obtained from commercial suppliers.

Preparation of *N*-Toluenesulfonylazetidinol 1a and 1a-*d*

To a dichloromethane solution (20 mL) of 3-hydroxyazetidine hydrochloride (1.2 g, 11 mmol) and triethylamine (3.1 mL, 22 mmol) was added *p*-toluenesulfonyl chloride (1.9 g, 10 mmol). After being stirred at room temperature for 12 h, HCl aq. (2N) was added to the reaction mixture. The organic layer was separated and the remaining aqueous layer was extracted with dichloromethane (3 times). The combined organic layer was washed with brine (once), dried over MgSO₄ and concentrated under reduced pressure. The residue was purified by Flash column chromatography on silica gel (hexane/ethyl acetate = 1/1) to afford the *N*-toluenesulfonylazetidinol **8a** (1.5 g, 6.6 mmol, 66% yield).

^1H NMR: δ = 2.13 (bs, 1H), 2.45 (s, 3H), 3.50-3.61 (m, 2H), 3.94-4.04 (m, 2H), 4.42-4.52 (m, 1H), 7.37 (d, J = 8.4 Hz, 2H), 7.72 (d, J = 8.4 Hz, 2H); ^{13}C NMR: δ = 21.6, 60.2, 60.5, 128.4, 129.8, 131.3, 144.3; HRMS (ESI^+): Calcd for $\text{C}_{10}\text{H}_{14}\text{NO}_3\text{S}$, $\text{M}+\text{H}^+$ 228.0689, Found m/z 228.0686; IR (ATR): 3501, 1331, 1144, 1049, 665 cm^{-1} .

^1H NMR: δ = 2.83 (bs, 1H), 3.49-3.55 (m, 2H), 3.89-3.96 (m, 2H), 4.35-4.44 (m, 1H); ^{13}C NMR: δ = 19.5-20.2 (m), 60.1, 60.2, 127.9 (t, $J_{\text{C-D}}$ = 24.7 Hz), 129.4 (t, J = 24.7 Hz), 130.8, 144.1; HRMS (ESI^+): Calcd for $\text{C}_{10}\text{H}_7\text{D}_7\text{NO}_3\text{S}$, $\text{M}+\text{H}^+$ 235.1128, Found m/z 235.1125; IR (ATR): 3503, 1333, 1142, 1059, 638 cm^{-1} .

^1H NMR: δ = 2.77 (bs, 1H), 3.57-3.64 (m, 2H), 4.00-4.07 (m, 2H), 4.41-4.50 (m, 1H), 7.21 (dd, J = 4.8, 4.0 Hz, 1H), 7.62 (dd, J = 3.6, 1.2 Hz, 1H), 7.71 (dd, J = 5.2, 1.2 Hz, 1H); ^{13}C NMR: δ = 60.0, 60.6, 127.9, 133.2, 133.5, 133.8; HRMS (ESI^+): Calcd for $\text{C}_7\text{H}_{10}\text{D}_7\text{NO}_3\text{S}_2$, $\text{M}+\text{H}^+$ 220.0097, Found m/z 220.0094; IR (ATR): 3476, 1325, 1148, 1038, 737 cm^{-1} .

To a dichloromethane solution (20 mL) of *N*-toluenesulfonylazetidinol **8** (780 mg, 3.4 mmol) was added Dess-Martin reagent (1.5 g, 3.5 mmol). After being stirred for 12 h at room temperature, saturated Na₂CO₃ aq. was added to the reaction mixture. The organic layer was separated and the remaining aqueous layer was extracted with dichloromethane (3 times). The combined organic layer was washed with brine (once), dried over MgSO₄ and concentrated.

The residue was dissolved in THF (20 mL). PhMgBr (1.0 M in THF, 5 mL, 5 mmol) was added therein at -78 °C and the reaction mixture was then allowed to be at room temperature. After being stirred for 3 h, HCl (2N) was added to the reaction mixture at 0 °C. The aqueous layer was extracted with AcOEt (3 times), washed with brine (once), dried over MgSO₄ and concentrated. The residue was purified by Flash column chromatography on silica gel (hexane/ethyl acetate = 3/1) to afford the *N*-toluenesulfonylazetidinol **1a** (600 mg, 2.0 mmol, 59 % yield).

¹H NMR: δ = 1.62 (s, 1H), 2.47 (s, 3H), 3.97 (d, *J* = 9.2 Hz, 2H), 4.13 (d, *J* = 9.2 Hz, 2H), 7.28-7.37 (m, 5H), 7.39 (d, *J* = 8.4 Hz, 2H), 7.78 (d, *J* = 8.0 Hz, 2H); ¹³C NMR: δ = 21.6, 65.2, 70.3, 124.4, 128.1, 128.4, 128.6, 129.9, 131.2, 142.0, 144.4; HRMS (ESI⁺): Calcd for C₁₆H₁₈NO₃S, M+H⁺ 304.1002, Found *m/z* 304.0995; IR (ATR): 3477, 1333, 1184, 1148, 671 cm⁻¹.

The spectral characteristics of **1a** were in agreement with the previously reported data.¹⁵

¹H NMR: δ = 2.50 (bs, 1H), 3.97 (d, *J* = 9.2 Hz, 2H), 4.13 (d, *J* = 9.2 Hz, 2H), 7.27-7.36 (m, 5H); ¹³C NMR: δ = 20.3-21.1 (m), 65.2, 70.3, 124.4, 128.1 (t, *J*_{C-D} = 24.7 Hz), 128.1, 128.6, 129.4 (t, *J*_{C-D} = 24.7 Hz), 131.1, 142.0, 144.1; HRMS (ESI⁺): Calcd for

$\text{C}_{16}\text{H}_{11}\text{D}_7\text{NO}_3\text{S}$, $\text{M}+\text{H}^+$ 311.1441, Found m/z 311.1434; IR (ATR): 3481, 1335, 1142, 702, 648 cm^{-1} .

**1b**

^1H NMR: δ = 2.32 (bs, 1H), 4.00-4.08 (m, 2H), 4.16-4.24 (m, 2H), 7.24 (dd, J = 4.8, 3.6 Hz, 1H), 7.30-7.37 (m, 5H), 7.68 (dd, J = 4.0, 1.6 Hz, 1H), 7.73 (dd, J = 4.8, 1.2 Hz, 1H); ^{13}C NMR: δ = 65.6, 70.2, 124.4, 128.0, 128.3, 128.8, 133.1, 133.87, 133.92, 141.7; HRMS (ESI^+): Calcd for $\text{C}_{13}\text{H}_{14}\text{NO}_3\text{S}_2$, $\text{M}+\text{H}^+$ 296.0410, Found m/z 296.0404; IR (ATR): 3524, 1333, 1161, 1148, 748 cm^{-1} .

Preparation of *N*-Toluenesulfonylazetidinol **1e**: A Typical Procedure of **1e**, and **1l-1n**

Preparation of α-Diazo Ketone **5a**: A Typical Procedure for Preparation of **5a-5c**

N-toluenesulfonylalanine **4a** (2.4 g, 10 mmol) was prepared according to the reported procedure.¹⁶ The resulting **4a** was dissolved in dichloromethane (50 mL). The mixture was cooled to 0 °C under argon atmosphere, and oxalyl chloride (1.3 mL, 15 mmol) and one-drop of *N,N*-dimethylformamide were added. After being stirred at room temperature for 12 h, solvent was removed under reduced pressure.

The residue was dissolved in THF under argon atmosphere. Diazomethane (which was freshly prepared by diazald and KOH, 25 mmol) in Et₂O was added to the solution at 0 °C. After being stirred for 3 h at room temperature, water was added to the reaction mixture. The organic layer was separated and the remaining aqueous layer was extracted with ethyl acetate (3 times). The combined organic layer was washed with brine (once), dried over MgSO₄ and concentrated. The residue was purified by Flash column chromatography on silica gel (hexane/ethyl acetate = 2/1 to 1/1) to afford the α-diazo ketone **5a** (1.5 g, 5.6 mmol, 56 % yield).

¹H NMR: δ = 1.26 (d, J = 7.2 Hz, 3H), 2.42 (s, 3H), 3.78-3.90 (m, 1H), 5.37-5.52 (m,

2H), 7.30 (d, $J = 8.4$ Hz, 2H), 7.72 (d, $J = 8.4$ Hz, 2H); ^{13}C NMR: $\delta = 19.4, 21.5, 53.9, 55.4, 127.1, 129.7, 136.8, 143.8, 192.8$; HRMS (ESI $^{+}$): Calcd for $\text{C}_{11}\text{H}_{14}\text{N}_3\text{O}_3\text{S}$, $\text{M}+\text{H}^{+}$ 268.0750, Found m/z 268.0747; IR (ATR): 2112, 1639, 1337, 1319, 1161 cm^{-1}

[α]_D²⁵ = 6.8 (c = 0.30, in CHCl₃); Enantiomeric excess was determined by HPLC with a Daicel Chiralpak IC, hexane/*i*-PrOH = 70/30, flow rate = 0.6 mL/min, λ = 260 nm): *t*₁ = 12.8 min (minor), *t*₂ = 15.3 min (major), er > 99:1.

Preparation of *N*-Toluenesulfonylazetidinol **1g**: A Typical Procedure for Preparation of **1g-1k**

Preparation of α -Diazo Ketone **5d**

The *N*-benzyloxycarbonylalanine **4d** (6.7 g, 30 mmol) was dissolved in THF (150 mL). Triethylamine (6 mL) and ethyl chlorocarbonate were added therein at -15 °C. Diazomethane in Et₂O (which was freshly prepared by diazald and KOH, 70 mmol) was added. The mixture was stirred at room temperature for 3 h, and then, water was added. The mixture was extracted with AcOEt, washed with water and brine, dried over MgSO₄ and concentrated. The residue was washed with Et₂O to afford the α -diazo ketone (5.9 g, 24 mmol, 80 % yield).

¹H NMR: δ = 1.34 (d, *J* = 6.8 Hz, 3H), 4.20-4.36 (m, 1H), 5.04-5.16 (m, 2H), 5.34-5.64 (m, 2H), 7.28-7.36 (m, 5H); ¹³C NMR: δ = 18.4, 53.5 (2C), 66.9, 128.0, 128.2, 128.5, 136.1, 155.6, 193.8; HRMS (ESI⁺): Calcd for C₁₂H₁₄N₃O₃, M+H⁺ 248.1030, Found m/z 248.1028; IR (ATR): 2116, 1717, 1636, 1533, 1252 cm⁻¹.

[α]_D²⁸ = -43.4 (c = 0.85, in CHCl₃).

The spectral characteristics of **5d** were in agreement with the previously reported data.¹⁸

Preparation of *N*-Benzyloxycarbonylazetidinone **6d**

To a dichloromethane solution (50 mL) of α -diazo ketone **5d** (2.5 g, 10 mmol) at 0 °C was added $\text{Rh}_2(\text{OAc})_4$ (20 mg, 0.05 mmol, 0.5 mol %). The reaction mixture was then warmed to room temperature. After being stirred for 12 h, solvent was removed under reduced pressure. The residue was purified by GPC to afford *N*-benzyloxycarbonylazetidinone **6d** (1.2 g, 5.6 mmol, 56% yield).

^1H NMR: δ = 1.49 (d, J = 7.2 Hz, 3H), 4.66 (dd, J = 16.4, 4.0 Hz, 1H), 4.77 (d, J = 16.4 Hz, 1H), 4.98-5.05 (m, 1H), 5.13-5.21 (m, 2H), 7.31-7.39 (m, 5H); ^{13}C NMR: δ = 15.3, 67.4, 68.7, 79.0, 128.1, 128.3, 128.6, 136.1, 156.3, 199.8; HRMS (ESI⁺): Calcd for $\text{C}_{12}\text{H}_{14}\text{NO}_3$, $\text{M}+\text{H}^+$ 220.0968, Found m/z 220.0966; IR (ATR): 1811, 1690, 1410, 1342, 696 cm^{-1} .

$[\alpha]_D^{29} = 39.0$ (c = 0.68, in CHCl_3).

Preparation of *N*-Benzyloxycarbonylazetidinol **7a and **7b****

To a THF solution (20 mL) of *N*-benzyloxycarbonylazetidinone **6d** (1.1 g, 5.0 mmol) at -78 °C was added PhMgBr (1.0 M in THF, 5.5 mL, 5.5 mmol). The reaction mixture was then warmed to room temperature. After being stirred for 3 h, HCl aq (2N) was added at 0 °C. The mixture was separated and the aqueous layer was extracted with AcOEt (3 times). The combined organic phase was washed with brine (once), dried over MgSO_4 and concentrated. The residue was purified by Flash column chromatography on silica gel (hexane/ethyl acetate = 1/1) to afford the *N*-benzyloxycarbonyl azetidinol **7a** (1.4 g, 4.8 mmol, 96% yield).

^1H NMR: δ = 1.50 (d, J = 6.4 Hz, 3H), 2.51 (bs, 1H), 4.11 (d, J = 9.6 Hz, 1H), 4.34 (d, J = 9.6 Hz, 1H), 4.58 (q, J = 6.4 Hz, 1H), 5.07-5.18 (m, 2H), 7.29-7.46 (m, 10H); ^{13}C NMR: δ = 14.2, 62.3, 66.7, 68.9, 73.0, 124.6, 127.8, 127.9, 128.0, 128.5, 128.7, 136.6,

143.4, 156.5; HRMS (ESI⁺): Calcd for C₁₈H₂₀NO₃, M+H⁺ 298.1438, Found m/z 298.1433; IR (ATR): 1670, 1423, 1248, 1016, 702 cm⁻¹.

[α]_D²⁹ = 4.6 (c = 0.89, in CHCl₃).

¹H NMR: δ = 1.49 (d, *J* = 6.4 Hz, 3H), 2.26 (bs, 1H), 3.81 (s, 3H), 4.09 (d, *J* = 9.6 Hz, 1H), 4.32 (d, *J* = 9.6 Hz, 1H), 4.52-4.61 (m, 1H), 5.06-5.18 (m, 2H), 6.87-6.94 (m, 2H), 7.26-7.39 (m, 7H); ¹³C NMR: δ = 14.3, 55.3, 62.2, 66.6, 68.7, 72.9, 114.0, 126.0, 127.8, 128.0, 128.5, 135.5, 136.6, 156.6, 159.3; HRMS (ESI⁺): Calcd for C₁₉H₂₂NO₄, M+H⁺ 328.1543, Found m/z 328.1539; IR (ATR): 1682, 1418, 1352, 1024, 696 cm⁻¹.

[α]_D²⁹ = 0.2 (c = 0.85, in CHCl₃).

Preparation of *N*-Toluenesulfonylazetidinol **1g**: A Typical procedure for Preparation of **1g-1k**

Pd/C (100 mg) was placed in a flask. A methanol (20 mL) solution of *N*-benzyloxycarbonylazetidinol **7a** (5 mmol, 1.5 mmol) was added therein and the flask was purged with hydrogen. After being stirred at room temperature for 12 h, the reaction mixture was passed through a pad of celite[®]. The solvent was removed under reduced pressure.

The residue was dissolved in dichloromethane (20 mL), and *p*-methoxyphenylsulfonyl chloride (1.0 g, 5.0 mmol) and NEt₃ (700 mL, 5 mmol) were added. The reaction mixture was stirred for 12 h and then water was added. The aqueous layer was extracted with dichloromethane (3 times), washed with brine (once), dried over MgSO₄ and concentrated. The residue was purified by flash column chromatography on silica gel (hexane/ethyl acetate = 3/1) to afford the *p*-methoxyphenylazetidinol **1g** (960 mg, 2.9 mmol, 58% yield).

^1H NMR: δ = 1.41 (d, J = 6.4 Hz, 3H), 2.59 (bs, 1H), 3.87 (dd, J = 9.2, 0.8 Hz, 1H), 3.90 (s, 3H), 3.99 (d, J = 9.2 Hz, 1H), 4.19 (q, J = 6.0 Hz, 1H), 6.98-7.07 (m, 4H), 7.20-7.27 (m, 3H), 7.79-7.85 (m, 2H); ^{13}C NMR: δ = 14.3, 55.7, 62.7, 70.1, 73.1, 114.4, 124.7, 126.5, 128.0, 128.5, 130.6, 141.6, 163.5; HRMS (ESI⁺): Calcd for $\text{C}_{17}\text{H}_{20}\text{NO}_4\text{S}$, $\text{M}+\text{H}^+$ 334.1108, Found m/z 334.1102; IR (ATR): 3470, 1595, 1333, 1153, 671 cm^{-1} .

Details for X-ray Crystallography

Single crystal of **2e** was obtained from hexane/dichloromethane solution and mounted on a glass capillary. The data was collected on a Rigaku R-Axis imaging plate area detector with graphite-monochromated Mo $K\alpha$ radiation operating at 50 kV and 40 mA at -173 °C. All the following procedure for analysis, Yadokari-XG¹⁹ was used as a graphical interface. The structure was solved by direct methods with SIR-97²⁰ and refined by full-matrix least-squares techniques against F^2 (SHELXL-97).²¹ All non-hydrogen atoms were refined anisotropically. The positions of hydrogen atoms were calculated, and their contributions in structural factor calculations were included.

Chapter 3

Stereoselective Synthesis of (*E*)-(Trisubstituted alkenyl)borinic Esters: Stereochemistry Reversed by Ligand in the Palladium-Catalyzed Reaction of Alkynylborates with Aryl Halides

Abstract

The palladium-catalyzed reaction of alkynylborates with aryl halides stereoselectively gave (*E*)-(trisubstituted alkenyl)-9-BBNs, in which two different aryl groups were installed *trans* to each other.

Introduction

Organoboron compounds are stable and easily handled organometallics with well understood reactivities, rendering them indispensable synthetic reagents for carbon–carbon bond formation.¹ In addition, organoboron compounds have found increasing applications in the fields of pharmaceutical chemistry² and materials science.³ Therefore, the development of efficient methods to prepare them is of even higher demand than ever.

Well established preparative methods exist for the synthesis of (monosubstituted alkenyl)(diorganyl)boranes such that these compounds have been widely applied for the synthesis of unsaturated organic compounds like allylic alcohols.⁴ However the selective preparation of both stereoisomers of (trisubstituted alkenyl)(diorganyl)boranes remains a significant challenge.^{5,6} We have reported that alkynyl(triaryl)borates (aryl = Ar¹) react with aryl halides (Ar²–X) in the presence of a palladium catalyst to afford a (trisubstituted alkenyl)(diaryl)boranes, in which the two aryl groups (Ar¹ and Ar²) are incorporated *cis* to each other across the resulting carbon–carbon double bond.⁷ Considering the potential utility of these compounds, we embarked on the development of a complementary synthetic method for the (*E*)-isomers. In this communication, we describe the stereoselective synthesis of (*E*)-(trisubstituted alkenyl)-9-BBNs by a palladium-catalyzed reaction of alkynylborates with aryl halides, in which the two different aryl groups are installed *trans* to each other.

Results and Discussion

Alkynylborate **1a** was readily prepared by the reaction of Ph-9-BBN with but-1-ynyllithium in THF,⁸ and subsequent cation exchange with tetramethylammonium chloride in methanol (Scheme 1). Borate **1a** obtained is a white precipitate of high purity, stable to air and moisture, and therefore, storable without any decomposition for several months.

Scheme 1. Preparation of Alkynyl Borate **1a**^a

^a Reagents and conditions: (a) THF, - 78 °C to rt, 1 h. (b) Me₄NCl, MeOH, rt, 5 min

Alkynylborate **1a** thus derived from Ph-9-BBN is preferred over the corresponding alkynyltriarylborate as the starting substance from a synthetic point of view. It was subjected to the palladium-catalyzed reaction with 4-bromoanisole in the presence of various phosphine ligands (Table 1). When tri(*o*-tolyl)phosphine was employed as the ligand, the phenyl group on boron underwent 1,3-migration onto the palladium in preference to the bridgehead sp^3 carbons of the 9-BBN moiety, and the (*Z*)-isomer was stereoselectively formed, as with the case of the corresponding triphenylborate.^{7a} Although we attempted to isolate the produced triorganoborane **3a**, it failed because **3a** was prone to decompose in air. Instead, **3a** was immediately hydrolyzed with acetic acid⁹ to give the alkene (*Z*)-**4a** (*E/Z* = 3/97, entry 1). The *E/Z* ratio changed in favor of the (*E*)-isomer as the steric bulkiness of the monodentate phosphine increased (entries 2-4). Surprisingly, the stereochemical preference was reversed for the (*E*)-isomer (*E/Z* = 92/8) when bidentate ligand DPEPhos having a large bite angle was used (entry 5). Finally, it was found that XANTPhos, possessing an even larger bite angle exclusively gave (*E*)-**4a** in 73% yield (entry 6).

Table 1. Ligand Screening^a

entry	ligand	yield of 4a / % ^b	<i>E/Z</i> of 4a ^b
1	P(<i>o</i> -tol) ₃	69	3/97
2	P(<i>t</i> -Bu) ₃	47	17/83
3	1-[(<i>t</i> -Bu) ₂ P](biphenyl)	18	28/72
4	2-[(<i>t</i> -Bu) ₂ P](1,1'-binaphthyl)	21	67/33
5	DPEPhos	24	92/8
6	XANTPhos	73	>1/99

^a reaction conditions: 1.0 equiv of **1a**, 1.05 equiv of **2a**, 2.5 mol % of [Pd(π -allyl)Cl]₂, 6 mol % of Ligand, toluene, 70 °C, 30 min; then AcOH, rt, 3 h. ^b Determined by GC analysis

Thus, the stereochemistry of the product depended strongly on the phosphine ligand employed. A proposed mechanism for the *trans*-addition reaction is shown in Scheme 2;

(i) oxidative addition of 4-bromoanisole (**2a**) to palladium(0) gives arylpalladium bromide **A**, (ii) arylpalladium species **A** is coordinated by alkynylborate **1a** to form intermediate **B**, (iii) carbopalladation across the carbon–carbon triple bond occurs in a *cis* fashion to provide alkenylpalladium **C**, (iv) a phenyl group on boron migrates to the α -carbon with inversion of stereochemistry,^{10,11} resulting in the formation of *trans*-addition product **3a** with regeneration of the palladium(0).¹²

Scheme 2. Proposed Mechanism

The ligand-dependent reaction pathway of the phenyl migration is explained as follows. Tri(*o*-tolyl)phosphine is relatively less stereo-demanding and, when located around the palladium center, provides enough space for the phenyl group on boron to undergo 1,3-migration to palladium (Scheme 4). On the other hand, a bulky bidentate ligand XANTPhos likely disfavors the 1,3-phenyl migration from boron to palladium. Instead, the direct 1,2-migration of the phenyl group from boron onto the α -carbon dominates,¹⁰ giving *trans*-addition product. Tri(*t*-butyl)phosphine and Buchwald type ligands, which are intermediates between tri(*o*-tolyl)phosphine and XANTPhos in sterics, may permit both of these pathways, resulting in a mixture of *E/Z* isomers.

Next, we tried to isolate the addition product in a form of an alkenylborane which was applicable to subsequent synthetic transformations rather than losing a carbon–boron linkage by hydrolysis. When the reaction mixture was directly subjected to a migrative oxidation reaction with trimethylamine-*N*-oxide, (trisubstituted alkenyl)borinic ester **5a** in which the bridgehead sp^3 carbon migrated onto oxygen was obtained stereoselectively.¹³ The resulting borinic ester (*E*)-**5a** was stable enough to be isolated by column chromatography on silica gel and could be stored without any decomposition for a longer period of time than 1 month. Most importantly, this reagent could be employed for subsequent carbon–carbon bond forming reactions (*vide infra*).

A wide variety of borinic esters were synthesized using the palladium/XANTPhos system followed by migrative oxidation with trimethylamine-*N*-oxide (Scheme 3). Aryl

halides having either an electron-donating or an electron-withdrawing substituent gave the corresponding borinic esters in good yields (**5a** and **5b**). Phthalimide (**5c**), chloro (**5f**, **5j**, and **5l**), and ester (**5i**) groups remained intact under the reaction conditions. A sterically demanding aryl iodide was also reactive (**5d**). In addition to the substituted phenyl groups, 2- and 3-bromothiophene afforded the desired product in good yield (**5e** and **5h**). Primary alkyl (**5a** to **5g**, **5l**, and **5m**), secondary alkyl (**5h** to **5k**), and aryl (**5n**) groups can be used as the substituent of the alkynyl moiety. The scope of the aryl group on boron was also broad; electron-rich (**5g** and **5n**) and -deficient (**5f**) phenyl and thienyl (**5l**) groups successfully participated in the migration reaction.

Table 2. Synthesis of Borinic Esters

^a Reaction conditions: 1.0 equiv of alkynylboronate **1**, 1.05 equiv of aryl halide **2**, 1 mol % of (xantphos)PdCl(π-allyl), toluene, 70 °C, 30 min; then 1.5 equiv of Me₃NO, DCM, rt, 2 h. Isolated yields were shown. The major isomers shown in the table were observed >95/5 ratio by NMR analysis. ^b Aryl iodide was used

Finally, we applied this reaction to the synthesis of both isomers of Tamoxifen (Scheme 5), which has been in clinical use for cancer treatment.^{14,15} The reaction of **1a** with bromobenzene with the palladium/tri(*o*-tolyl)phosphine catalyst followed by oxidation with trimethylamine-*N*-oxide gave borinic ester (*Z*)-**5o** (71% yield, *E/Z* = 7/93). On the other hand, the corresponding (*E*)-isomer was stereoselectively obtained in 83% yield (*E/Z* = >95/5) when the reaction of **1a** with bromobenzene was carried out with the palladium/XANTPhos catalyst, the loading of which could be decreased even

to 0.1 mol%. The Suzuki-Miyaura coupling reaction of each stereoisomer of **5o** with 1-bromo-4-[2-(*N,N*-dimethylamino)ethoxy]benzene (**2b**) afforded Tamoxifen (**6**) with retention of the each stereochemistry. Thus, the present study made it possible to synthesize either stereoisomer of tetrasubstituted olefins¹⁶ starting from the same substances by choice of the appropriate ligand.

Scheme 3. Synthesis of Tamoxifens^a

^a Reagents and conditions: (a) 1 mol % of (*o*-tol)₃PPdCl(π -allyl), toluene, 70 °C, 30 min; then 1.5 equiv of Me₃NO, DCM, rt, 2 h. (b) 0.1 mol % of (xantphos)PdCl(π -allyl), toluene, 70 °C, 30 min; then 1.5 equiv of Me₃NO, DCM, rt, 2 h. (c) 1.05 equiv of 4-BrC₆H₄[O(CH₂)₂NMe₂] (**2b**), 2.5 mol % of Pd(OAc)₂, 5 mol % of SPhos, K₃PO₄, THF, 60 °C, 12 h for (*E*)-**5o**, 24 h for (*Z*)-**5o**

Conclusions

In summary, we have developed a new catalyst system for the palladium-catalyzed reaction of alkynylborates with aryl halides, which produces (*E*)-(trisubstituted alkenyl)boranes stereoselectively. With both stereoisomers being available, the reinforced palladium-catalyzed reaction of alkynylborates serves as an authentic method for the synthesis of (trisubstituted alkenyl)boron compounds.

Experimental Section

General. NMR spectra were recorded on a Varian Gemini 2000 (^1H at 300 MHz and ^{13}C at 75 MHz) or Varian Mercury-400 (^1H at 400 MHz and ^{11}B at 128 MHz) spectrometers. Unless otherwise noted, CDCl_3 was used as a solvent. Chemical Shifts are recorded in δ ppm referenced to a residual CDCl_3 ($\delta = 7.26$ for ^1H , $\delta = 77.0$ for ^{13}C), CD_3CN ($\delta = 1.94$ for ^1H , $\delta = 1.32$ for ^{13}C), and $\text{BF}_3 \cdot \text{OEt}_2$ ($\delta = 0.00$ for ^{11}B). High-resolution mass spectra were recorded on JEOL JMS-SX102A spectrometer. Infrared spectra were recorded on SHIMADZU FT-IR 8100. Column chromatography was performed with silica gel 60 N (Kanto). Preparative thin-layer chromatography was performed with Silica gel 60 PF₂₅₄ (Merck).

Materials. Unless otherwise noted, all chemicals and anhydrous solvents were obtained from commercial suppliers and used as received. Toluene was dried over Na-benzophenone ketyl. AcOH was degassed by N_2 bubbling. (XANTPhos)Pd(π -allyl)Cl¹⁷ and Ph-9-BBN¹⁸ were prepared according to the reported procedures.

Preparation of alkynylborates **1a**.

To a stirred solution of 1-butyne (1 ml) in THF (8.0 ml) at $-78\text{ }^{\circ}\text{C}$ was added *n*-BuLi (1.6 M in hexane, 3.4 ml, 5.5 mmol). After 30 minutes at this temperature, Ph-9-BBN (990 mg, 5.0 mmol) was added and the cooling bath was then removed. After being stirred for 1 h at room temperature, the reaction was quenched by adding a small amount of methanol. Then, volatile materials were removed under reduced pressure. The residue was dissolved in methanol and tetramethylammonium chloride (600 mg, 5.5 mmol) was added with stirring at $-78\text{ }^{\circ}\text{C}$, resulting in white solid. It was collected by filtration and washed with cold methanol to give alkynylborate **1a** (1.2 g, 3.7 mmol, 74% yield).

^1H NMR (CD_3CN): δ = 0.92 (bs, 2H), 0.97 (t, J = 7.8 Hz, 3H), 1.11-1.20 (m, 1H), 1.36-2.07 (m, 11H), 2.36-2.50 (m, 2H), 3.03 (s, 12 H), 6.79-6.86 (m, 1H), 7.00-7.07 (m, 2H), 7.35 (d, J = 7.2 Hz, 2H); ^{13}C NMR (CD_3CN): δ = 14.9, 16.6, 26.6 (q, $J_{\text{C-B}}$ = 37.9 Hz), 27.1, 27.5, 32.4, 34.9, 56.1, 94.8, 122.1, 126.9, 133.9; ^{11}B NMR: δ = -13.3; HRMS (FAB) Calcd for $\text{C}_{18}\text{H}_{24}\text{B}$ [M-(NMe $_4$)] 251.1971. Found 251.1975.

Preparation of alkynylborates 1b: A typical procedure for the preparation of alkynylborates 1b-1h.

To a stirred solution of 1-pentyne (375 mg, 5.5 mmol) in THF (8.0 ml) at $-78\text{ }^\circ\text{C}$ was added $n\text{-BuLi}$ (1.6 M in hexane, 3.4 ml, 5.5 mmol). After 30 minutes at this temperature, 4-ClC $_6$ H $_4$ -9-BBN (1.16 g, 5.0 mmol) was added and the cooling bath was removed. After being stirred for 1 h at room temperature, the reaction was quenched by adding a small amount of methanol. Then, volatile materials were removed under reduced pressure. The residue was dissolved in methanol and tetramethylammonium chloride (600 mg, 5.5 mmol) was added with stirring at $-78\text{ }^\circ\text{C}$, resulting in white solid. It was collected by filtration and was washed with cold methanol to give alkynylborate **1b** (1.05g, 2.8 mmol, 56% yield).

Palladium-Catalyzed Reaction of Alkynylborate **1a with 4-Bromoanisole. Typical Procedure for the Ligand Screening.**

Under an argon atmosphere, a toluene solution (1.0 ml) of alkynylborate **1a** (65.1 mg, 0.20 mmol), $[\text{Pd}(\pi\text{-allyl})\text{Cl}]_2$ (1.8 mg, 5 μmol), $\text{P}(o\text{-tol})_3$ (3.7 mg, 12 μmol) and 4-bromoanisole **2a** (39.3 mg, 0.21 mmol) was stirred for 30 minutes at 70 $^\circ\text{C}$. To the reaction mixture was added AcOH at room temperature. After being stirred for 3 h, the resulting mixture was neutralized with saturated Na_2CO_3 solution. The aqueous layer was extracted with AcOEt (3 times), washed with water (once), brine (once), dried over MgSO_4 and concentrated. A portion of the sample was taken in a GC tube and diluted with Et_2O to determine the GC yields.

Palladium/XANTPhos-Catalyzed Reaction of Alkynylborate **1a with 4-Bromoanisole. A Typical Procedure for the Palladium/XANTPhos-Catalyzed Reaction of Alkynylborates with Arylhalides.**

Under an argon atmosphere, a toluene solution (1.0 ml) of alkynylborate **1a** (65.1 mg, 0.20 mmol), (XANTPhos)Pd(π-allyl)Cl (1.5 mg, 2.0 μmol), and 4-bromoanisole **2a** (39.3 mg, 0.21 mmol) was stirred for 30 minutes at 70 °C. To the reaction mixture were added Me₃NO (22.5 mg, 0.30 mmol) and CH₂Cl₂ (1.0 ml) at room temperature. After being stirred for 2 h, the resulting mixture was passed through a pad of Florisil and eluted with ethyl acetate. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 50/1) to afford the (trisubstituted alkenyl)borinic ester **5a** (61.9 mg, 0.17 mmol, 83% yield, *E/Z* = >95/5).

¹H NMR: δ = 0.80 (t, *J* = 7.8 Hz, 3H), 1.02-1.71 (m, 13H), 2.27 (q, *J* = 7.8 Hz, 2H), 3.83 (s, 3H), 4.38-4.44 (m, 1H), 6.85-6.91 (m, 2H), 7.14-7.36 (m, 7H); ¹³C NMR: δ = 13.8, 22.1, 26.7, 27.3 (br), 27.7, 31.2, 55.3, 73.6, 113.2, 125.1, 127.8, 128.3, 129.8, 136.6, 143.6, 149.4, 158.6; ¹¹B NMR: δ = 50.0; HRMS (EI) Calcd for C₂₅H₃₁BO₂ (M⁺) 374.2417 Found 374.2410.

Palladium/Tri(*o*-tolyl)phosphine-Catalyzed Reaction of Alkynylborate **1a** with 4-Bromobenzene.

Under an argon atmosphere, a toluene solution (2.0 ml) of alkynylborate **1a** (195.2 mg, 0.60 mmol), (*o*-tol) $_3$ PPd(π -allyl)Cl (3.0 mg, 6.0 μmol), and 4-bromobenzene (98.9 mg, 0.63 mmol) was stirred for 30 minutes at 70 $^\circ\text{C}$. To the reaction mixture were added

Me₃NO (67.8 mg, 0.90 mmol) and CH₂Cl₂ (2.0 ml) at room temperature. After being stirred for 2 h, the resulting mixture was passed through a pad of Florisil and eluted with ethyl acetate. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 50/1) to afford the (trisubstituted alkenyl)borinic ester (Z)-**5b** (146.9 mg, 0.43 mmol, 71% yield, *E/Z* = 7/93).

¹H NMR: δ = 1.01 (t, *J* = 7.2 Hz, 3H), 1.39-2.00 (m, 13H), 2.67 (q, *J* = 7.2 Hz, 2H), 4.70-4.75 (m, 1H), 6.85-7.10 (m, 10H); ¹³C NMR: δ = 13.9, 22.4, 26.7, 31.3, 31.7, 74.0, 124.8, 125.7, 127.2, 127.4, 129.38, 129.41, 142.1, 142.5, 127.5; ¹¹B NMR: δ = 51.2; HRMS (EI) Calcd for C₂₄H₂₉BO (M⁺) 344.2311. Found 344.2310.

¹H NMR: δ = 0.81 (t, *J* = 7.2 Hz, 3H), 1.00-1.69 (m, 13H), 2.30 (q, *J* = 7.2 Hz, 2H), 4.38-4.43 (m, 1H), 7.18-7.37 (m, 10H); ¹³C NMR: δ = 13.7, 22.1, 26.6, 27.4 (br), 27.7, 31.2, 73.7, 125.3, 126.8, 127.8, 127.9, 128.3, 128.8, 143.3, 144.2, 149.4; ¹¹B NMR: δ = 50.4; HRMS (EI) Calcd for C₂₄H₂₉BO (M⁺) 344.2311. Found 344.2313.

Typical Procedure for Palladium-Catalyzed Reaction of Borinic Ester **5o** with Aryl Bromide **2b**.

Under an argon atmosphere, borinic ester (*E*)-**5o** (68.9 mg, 0.20 mmol), Pd(OAc)₂ (1.1 mg, 5.0 μmol), SPhos (4.1 mg, 1.0 μmol), and **2b** (51.2 mg, 0.21 mmol) in THF (1.0 ml) was stirred for 12 h at 60 °C. After cooling the reaction mixture to room temperature, water was added. The organic layer was separated and extracted with CH₂Cl₂ (3 times), and washed with water (once), brine (once), dried over Na₂SO₄ and concentrated. The residue was purified by preparative thin-layer chromatography on silica gel (CHCl₃/EtOH/NEt₃ = 100/5/1) to afford the (*Z*)-Tamoxifen **6** (63.3 mg, 0.17 mmol, 85 %, *E/Z* = >5/95). The spectral data was identical to that reported.¹⁹

- (11) Inversion of the stereochemistry was also observed in the palladium-catalyzed cross-coupling reaction of 2-bromo-1,3-dienes with organozinc reagents: Zeng, X.; Hu, Q.; Qian, M.; Negishi, E. *J. Am. Chem. Soc.* **2003**, *125*, 13636.
- (12) An alternative mechanism is conceivable; the arylpalladium bromide **A** acts as an

electrophile to place the palladium on the carbon β to boron and induces migration of a phenyl group on boron to the α -carbon. A similar mechanism has been assumed for analogous reactions of alkynylborates with alkyl halides, most of which lacked in stereoselectivity. The high stereoselectivity obtained in the present reaction led us to favor the mechanism proposed in the text.

Chapter 4

Iterative Approach to Oligo(arylenevinylene)s Containing Tetrasubstituted Vinylene Units

Abstract

Monodispersed oligo(arylenevinylene)s containing tetrasubstituted vinylene units were stereoselectively synthesized in an efficient manner by iteration of two different kinds of palladium-catalyzed reactions.

Introduction

It is one of current topics in organic synthesis to prepare structurally well-defined oligomeric compounds of higher molecular weight. Among various oligomers, oligo(phenylenevinylene)s (OPVs) are of significant interest and have been extensively studied in the field of organic electronics.¹ A wide variety of substituted OPVs have been synthesized and applied to optoelectronic devices such as organic light-emitting diodes² and organic solar cells.³ However, it is still a formidable task to synthesize oligo(arylenevinylene)s containing tetrasubstituted vinylene units due to the difficulty of constructing sterically congested vinylene units in a stereoselective manner.⁴ In this paper, we report an efficient and high yielding method to synthesize such oligo(arylenevinylene)s of single molecular weight.

Results and Discussion

Initially, 4-bromoanisole was treated with 1.0 equiv of alkynylborate **1a** in the presence of (xantphos)Pd(π -allyl)Cl (1 mol %), and (trisubstituted alkenyl)-9-BBN **2** was formed in a stereoselective manner, as we previously reported (Scheme 1).⁵ Although the product **2** contained an alkenylborane moiety, it did not couple with 4-bromoanisole in the absence of a base. After completion of the initial reaction with alkynylborate **1a**, 1.0 equiv of 4-bromoiodobenzene and 3 equiv of NaOH were directly added to the reaction mixture. The Suzuki-Miyaura coupling reaction took place chemoselectively at the iodo site to give tetrasubstituted olefin **3** in 87% yield with excellent stereoselectivity ($E/Z = <1/99$). The bromoaryl moiety was retained in the coupling product **3** due to the reactivity difference between the iodo and bromo groups.⁶ Thus, the Pd/XANTPHOS catalyst was proved to be active enough to promote the two different kinds of carbon-carbon bond forming reactions in one-pot without the need for any additional catalyst or ligand. Through this sequential one-pot procedure, the initial aryl bromide (*i.e.* 4-bromoanisole) grew into the second-generation aryl bromide **3**, which is expected to be directly used in the reaction with the borate **1a** again without intervention of any activation or deprotection step.

Scheme 1. One-Pot Synthesis of Tetrasubstituted Olefin

Next, aryl bromide **3** was subjected to the second-round sequential one-pot procedure. Treatment of **3** with alkynylborate **1a** (1.1 equiv) followed by direct addition of 4-bromoiodobenzene (1.1 equiv) and NaOH to the reaction mixture afforded the third-generation aryl bromide **4** in 92% yield (Scheme 2). Further application of the third-round sequential procedure to **4** furnished the fourth-generation aryl bromide **5** in 87% yield. The sequential procedure was repeated on **5** once to give the fifth-generation **6** in 82% yield, and twice to give the sixth-generation **7** in 85% yield. These oligomers were readily soluble in common organic solvents like toluene, THF, AcOEt and chloroform, and therefore, were isolated with high purity by column chromatography on silica gel, and identified by ^1H and ^{13}C NMR and mass spectroscopy. Importantly, the yield of each round did not decrease as the molecular size increased, suggesting that further elongation by the iterative method would be possible. Thus, one (tetrasubstituted vinylene)phenylene unit could be added to the chain in a stepwise manner with high efficiency and stereoselectivity by repetition of the sequential one-pot procedure.

Monodispersed oligomers can be divergently synthesized by repeating an iterative procedure which generally consists of an extension step and an activation step.^{1,7} An extending unit possessing a dormant coupling site is initially added to a main chain (an extension step). The dormant site is then activated to be subsequently coupled with another extending unit (an activation step). On the contrary, the present method to synthesize OPVs dispenses with the need for activation.⁸ One cycle adding a vinylene-phenylene unit consists of two different extension steps, one extending a tetrasubstituted vinylene unit and the other extending a phenylene unit. Both extension steps can be executed by the same catalyst system in one-pot. Thus, this simple method makes it practical to synthesize a structurally well-defined oligomer of single molecular weight in an efficient way.

Scheme 2. Repetition of the Sequential Procedure

A phenylenevinylene chain could be extended into two directions by using 1,4-dibromobenzene as the starting aryl bromide (Scheme 3). 1,4-Dibromobenzene was reacted with the alkynylborates **1a** (2.1 equiv) under the standard conditions, and the subsequent double cross-coupling reaction with 4-bromoiodobenzene (2.2 equiv) furnished the dibromide **8** in 86% yield. The dibromide **8** was then reacted with the alkynylborate **1a** (3.0 equiv) to afford diborylated phenylenevinylene intermediate, which was treated with 4-bromoiodobenzene (4.0 equiv) and NaOH, resulting in the

formation of OPV **9** in 92% yield. Interestingly, OPV **9** exhibited visible blue fluorescence in solution, whereas OPVs **4-7** did not. Thus, even a small structural change of the OPVs may cause a significant influence on their photophysical properties.

Scheme 3. Extention into Two Directions

Finally, the functional group compatibility of the palladium-catalyzed sequential procedure was exploited to synthesize the structurally diversified oligo(arylenevinylene) **12** (Scheme 4). 4-Bromotrimethylsilylbenzene was reacted with 1.0 equiv of the alkynylborate **1b** having a 4-methoxyphenyl group on boron, and the reaction mixture was then treated with 1.0 equiv of 4-bromo-2-fluoriodobenzene to give **10** in 88% yield. The second-round extension was carried out using the alkynylborate **1a** (1.1 equiv) and then 2,5-dibromothiophene (3.0 equiv) and NaOH. The bi(arylenevinylene) **11** possessing five different aryl groups and two alkyl groups was obtained in 84% yield. Furthermore, **11** was subjected to the third-round extension using 1.1 equiv of the alkynylborate **1c** with a 4-chlorophenyl group on boron and then 1.1 equiv of 4-(ethoxycarbonyl)iodobenzene to give the ter(arylenevinylene) **12** in 88% yield. The structure of **12** is highly diversified, consisting of seven different aryl groups and three alkyl groups. Thus, a wide variety of structural modification could be installed at desired positions by changing arylene and vinylene modules.

Scheme 4. Synthesis of Oligo(arylenevinylene) **12**

Conclusions

In conclusion, we have developed an efficient iterative method for the synthesis of oligo(arylenevinylene)s containing tetrasubstituted vinylene units. Of note is that an aryl bromide grew into the next generation aryl bromide in one-pot through two different kinds of extending steps. The method dispenses with the need of activation steps, and thus, rapidly increases the molecular complexity. Synthesis of new OPVs, and studies on structural features and photophysical properties are now in progress.

Experimental Section

General. NMR spectra were recorded on a Varian Gemini 2000 (^1H at 300 MHz and ^{13}C at 75 MHz), JEOL JNM-A500 (^1H at 500 MHz and ^{13}C at 150 MHz), or Varian 400-MR Auto Tune X5 (^{11}B at 128 MHz) spectrometers. Unless otherwise noted, CDCl_3 was used as a solvent. Chemical Shifts are recorded in δ ppm referenced to a residual CDCl_3 ($\delta = 7.26$ for ^1H , $\delta = 77.0$ for ^{13}C), CD_3CN ($\delta = 1.94$ for ^1H , $\delta = 1.32$ for ^{13}C), and $\text{BF}_3 \cdot \text{OEt}_2$ ($\delta = 0.00$ for ^{11}B). High-resolution mass spectra were recorded on Applied Biosystems Voyager Elite or JEOL JMS-HX110A spectrometer. Infrared spectra were recorded on a SHIMADZU FT-IR 8100. Column chromatography was performed with silica gel 60 N (Kanto). Preparative thin-layer chromatography was performed with Silica gel 60 PF_{254} (Merck). Gel permeation chromatography (GPC) was carried out with Japan Analytical Industry LC-908 or LC-9204.

Materials. Unless otherwise noted, all chemicals and anhydrous solvents were obtained from commercial suppliers. Toluene was dried over Na-benzophenone ketyl. $(\text{XANTPhos})\text{Pd}(\pi\text{-allyl})\text{Cl}$,⁹ Ar-9-BBN,¹⁰ and 5-Hexyn-1-yl(methoxymethyl)ether¹¹ were prepared according to the reported procedure.

Preparation of Alkynylborates 1a: A Typical Procedure for the Preparation of Alkynylborates 1a, 1b

To a stirred solution of 5-hexyn-1-yl(methoxymethyl)ether (2.04 g, 14.4 mmol) in THF (20.0 ml) at -78°C was added $n\text{-BuLi}$ (1.6 M in hexane, 9.0 ml, 14.4 mmol). After 30 minutes at this temperature, phenyl-9-BBN (2.60 g, 13.0 mmol) was added and the cooling bath was removed. After being stirred for 1 h at room temperature, the reaction was quenched by adding a small amount of methanol. Then, volatile materials were removed under reduced pressure. The residue was dissolved in methanol and tetramethylammonium chloride (1.60 g, 14.6 mmol) was added with stirring at -78°C , resulting in white solid. It was collected by filtration and was washed with cold methanol to give alkynylborate **1a** (3.20 g, 7.7 mmol, 60% yield).

^1H NMR (CD_3CN , 300 MHz): δ = 0.91 (bs, 2H), 1.10-1.19 (m, 1H), 1.32-1.96 (m, 15H), 2.02 (t, J = 6.6 Hz, 2H), 2.36-2.51 (m, 2H), 3.04 (s, 12H), 3.28 (s, 3H), 3.46 (t, J = 6.9 Hz, 2H), 4.54 (s, 2H), 6.78-6.85 (m, 1H), 6.98-7.05 (m, 2H), 7.34 (d, J = 7.2 Hz, 2H); ^{13}C NMR (CD_3CN , 75 MHz): δ = 21.0, 26.7 (br), 27.1, 27.5, 28.2, 29.7, 32.4, 34.9, 55.1, 56.1, 68.1, 92.8, 96.8, 122.1, 126.9, 133.8; ^{11}B NMR (128 MHz): δ = -18.0; HRMS (FAB) Calcd for $\text{C}_{22}\text{H}_{32}\text{BO}_2$ [$\text{M}-(\text{NMe}_4)^+$] 339.2495. Found 339.2493.

^1H NMR (CD_3CN , 300 MHz): δ = 0.88 (bs, 2H), 1.10-1.20 (m, 1H), 1.34-1.96 (m, 9H), 2.25 (t, J = 7.2 Hz, 2H), 2.34-2.49 (m, 2H), 2.63 (t, J = 7.2 Hz, 2H), 3.03 (s, 12H), 3.72 (s, 3H), 6.63-6.69 (m, 2H), 7.11-7.28 (m, 7H); ^{13}C NMR (CD_3CN , 100 MHz) δ = 24.2, 27.2, 27.5, 32.4, 34.9, 38.1, 55.4, 56.0, 112.9, 126.6, 128.9, 129.8, 134.6, 143.4, 156.3; ^{11}B NMR (128 MHz): δ = -18.2; HRMS (FAB) Calcd for $\text{C}_{25}\text{H}_{30}\text{BO}$ [$\text{M}-(\text{NMe}_4)^+$] 357.2390. Found 357.2383.

One-Pot Synthesis of Tetrasubstituted Olefin 3. A Typical Procedure for the Synthesis of Tetrasubstituted Oligo(arylenevinylene)s 3-12.

Under an argon atmosphere, a mixture of alkynylborate **1**, (XANTPhos)Pd(π -allyl)Cl (X mg, Y mmol), and aryl halide **A** in toluene was stirred for time t_1 at 50 °C. Then, aryl halide **B** and base **C** were added to the reaction mixture, which was stirred for time t_2 and water was added. After addition of water, the aqueous layer was extracted with AcOEt (3 times), washed with water (once), brine (once), dried over Na₂SO₄ and concentrated. The residue was purified by GPC to afford the tetrasubstituted oligo(arylenevinylene)s

alkynylborate **1**: **1a** (827 mg, 2.0 mmol), (XANTPhos)Pd(π -allyl)Cl (15 mg, 20 μ mol), aryl halide **A**: 4-bromoanisole (393 mg, 2.1 mmol), aryl halide **B**: 4-bromoiodobenzene (566 mg, 2.0 mmol), base **C**: NaOH (240 mg, 6.0 mmol), t_1 : 0.5 h, t_2 : 6 h

¹H NMR (300 MHz): δ = 1.30-1.58 (m, 4H), 2.41 (t, J = 7.8 Hz, 2H), 3.27 (s, 3H), 3.37 (t, J = 6.6 Hz, 2H), 3.76 (s, 3H), 4.52 (s, 2H), 6.67-6.75 (m, 4H), 6.97-7.02 (m, 2H), 7.09-7.36 (m, 7H); ¹³C NMR (75 MHz): δ = 25.5, 29.8, 35.6, 55.10, 55.14, 67.6, 96.4, 113.4, 119.6, 126.7, 128.2, 129.4, 130.46, 130.49, 132.3, 133.9, 137.6, 140.8, 142.0, 143.0, 158.0; HRMS (MALDI-TOF-MS (DCTB)) calcd for C₂₇H₂₉BrO₃ [M]⁺ 480.1300. Found 480.1269. The (Z)-stereochemistry was determined by the 2D NOESY spectroscopy.

alkynylborate **1**: **1a** (863 mg, 2.1 mmol), (XANTPhos)Pd(π -allyl)Cl (15 mg, 20 μ mol), aryl halide **A**: **3** (963 mg, 2.0 mmol), aryl halide **B**: 4-bromoiodobenzene (622 mg, 2.2 mmol), base **C**: NaOH (240 mg, 6.0 mmol), t_1 : 0.5 h, t_2 : 6 h

^1H NMR (300 MHz): δ = 1.24-1.54 (m, 8H), 2.33 (t, J = 7.8 Hz, 2H), 2.42 (t, J = 7.5 Hz, 2H), 3.25 (s, 3H), 3.29 (s, 3H), 3.31-3.41 (m, 4H), 3.80 (s, 3H), 4.51 (s, 2H), 4.53 (s, 2H), 6.62-6.78 (m, 8H), 6.97-7.03 (m, 2H), 7.06-7.38 (m, 12H); ^{13}C NMR (150 MHz): δ = 25.2, 25.4, 29.5, 29.6, 35.3, 35.4, 55.02, 55.04, 55.2, 67.5, 67.6, 96.29, 96.32, 113.1, 119.6, 126.5, 126.7, 128.1, 128.2, 128.5, 129.41, 129.42, 130.3, 130.4, 130.6, 132.4, 134.3, 137.7, 138.5, 139.0, 140.0, 141.3, 141.4, 141.8, 142.9, 143.5, 157.9; HRMS (MALDI-TOF-MS (DIT)) calcd for $\text{C}_{47}\text{H}_{51}\text{BrO}_5\text{Na}$ $[\text{M}+\text{Na}]^+$ 797.2818. Chapter 5

Regioselective Construction of Indene Skeletons by Palladium-Catalyzed Annulation of Alkynylborates with *o*-Iodophenyl Ketones

Abstract

A palladium-catalyzed annulation reaction of alkynylborates with *o*-iodophenyl ketones to form indenenes is described. Highly substituted indene skeletons are efficiently constructed with site-specific installation of substituents.

Introduction

Indenes are important structural motif found in a number of biologically active compounds.¹ For example, an indene framework with an *exo*-alkylidene moiety is imbedded in sulindac, which is a non-steroidal anti-inflammatory drug.^{1a} Dimethindene, an oral antihistamine agent, has an indene core tethered to an amine moiety.^{1b} In addition to these commercial medicines, indene derivatives have also been exploited as materials for optoelectronics² and ligands for transition metal complexes.³ Consequently, development of a new method to construct indene skeletons has been an attractive subject in organic synthesis.⁴

Alkynylboron compounds have been utilized as useful intermediates in organic synthesis.⁵ We have previously developed the palladium-catalyzed reaction of alkynylborates with aryl halides.⁶ (Trisubstituted alkenyl)boranes, which are otherwise difficult to synthesize, are readily obtained in a regio- and stereoselective fashion. Now, the palladium-catalyzed reaction is extended to the construction of indene skeletons. Alkynylborates react with *o*-iodophenyl ketones to afford 2,3-disubstituted indenols with specific installation of 2- and 3-substituents.

Results and Discussion

Alkynylborate **1a** and its constitutional isomer **1b** were prepared from the corresponding *B*-aryl-9-borabicyclo[3.3.1]nonane (Ar-9-BBN) and terminal alkyne according to the reported method.^{6c} The borate **1a** (1.0 equiv) was treated with *o*-iodoacetophenone (**2a**, 1.05 equiv) in the presence of (dpephos)Pd(*p*-allyl)Cl (1 mol %) at 50 °C for 1 h (Scheme 1). The reaction mixture was then treated with hydrogen peroxide to oxidize the organoboron residue. Purification by column chromatography on silica gel afforded 2,3-diarylindenol **3a** in 85% yield. In sharp contrast, the reaction of the borate **1b** with **2a** selectively provided the regioisomeric indenol **3b** in 88% yield. Thus, the present palladium-catalyzed reaction makes possible selective production of both regioisomers of 2,3-diarylindenols, which is difficult to perform using the conventional annulation reaction of *o*-halophenyl ketones with 1,2-diarylalkynes.^{4b}

Scheme 1. Reactions of Alkynylborates **1** and *o*-Iodoacetophenone **2a**

The selective formation of **3a** from **1a** and **2a** can be explained by the mechanism shown in scheme 2, which is based on the proposed mechanism of the palladium-catalyzed reaction of alkynylborates with simple aryl halides.^{6c} Oxidative addition of **2a** to palladium(0) forms arylpalladium **A**. Regioselective *cis*-carbopalladation across the carbon–carbon triple bond of **1a** gives alkenylpalladium **B**, so that the phenyl group on the anionic boron migrates onto the α -carbon. The carbon–palladium bond is substituted with inversion of the stereochemistry to afford alkenylborane **C**.⁷ The ketone moiety remains intact during the course of the palladium-catalyzed reaction. The generated *B*-alkenyl-9-BBN moiety undergoes intramolecular addition to the carbonyl group⁸ to form the boron indenolate **B**. Upon the following oxidative work-up with NaOH/H₂O₂, **B** is hydrolyzed to the indenol **3a**.

Scheme 2. Mechanism Proposed for the Formation of **3a**

The present reaction successfully furnished a wide variety of highly-substituted indenols (Table 1). For example, thiophene-substituted **3d** and alkyl-substituted **3e** were obtained in 82% and 92% yield, respectively. The use of *o*-iodobenzaldehyde and *o*-iodobenzophenone gave the corresponding indenols **3f** and **3g**. The indenols equipped with alkoxy, trifluoromethyl, and fluorine groups on the aromatic ring (**3h-i**) could also be synthesized.

Table 1. Synthesis of Indenols 3^a

^a Reagents and conditions: 1.0 equiv. of alkynylborates **1**, 1.05 equiv. of *o*-iodophenyl ketone **2**, 1 mol % of [(dpephos)PdCl(π -allyl)], toluene, 50 °C, 1 h; then aq. H₂O₂, aq. NaOH, MeOH, room temp., 2 h. Isolated yields are shown.

Alkenyl-substituted **3k** and alkyl-substituted **3l** were also synthesized from *B*-alkenyl-9-BBN **1c** and *B*-alkyl-9-BBN **1d**, respectively [Eqs. (1) and (2)]. The formation of **3l** is noteworthy from the mechanistic point of view; the *n*-butyl group on the anionic boron migrates onto the α -carbon in preference to the bridgehead sp³ carbon of the 9-BBN framework.⁹ This selectivity stands in sharp contrast to that observed in the reaction with iodine.¹⁰

It was possible to directly synthesize 2,3-dialkylindenol **3m** in one-pot starting from 1-octene, 4-phenylbut-1-yne and *o*-iodoacetophenone **2a** without isolation of the intermediates (Scheme 3). Hydroboration of 1-octene with H-9-BBN in THF afforded *B*-*n*-octyl-9-BBN, which was then treated with 4-phenylbut-1-ynyllithium to form the corresponding lithium alkynylborate. A toluene solution containing *o*-iodoacetophenone (**2a**) and (dpephos)Pd(p-allyl)Cl was added to the reaction mixture, which was heated at 50 °C for 1 h. Oxidative work-up and purification by column chromatography furnished **3m** in 91% isolated yield based on **2a**.

Scheme 3. Synthesis of indenol **3m** from 1-octene

The palladium-catalyzed annulation of **1a** with **2b** gave indenol **3n** in 74% yield, which was subjected to further derivatization (Scheme 4). Oxidation of **3n** with manganese(IV) oxide furnished the indenone **4**. The following Wolff-Kishner reaction

reduced the carbonyl group without isomerization of the double bond to give indene **5** in 59% yield.¹¹

Scheme 4. Synthesis of Indenone **4 and Indene **5****

Conclusions

We have described the palladium-catalyzed annulation reaction of alkynylborates with *o*-iodophenyl ketones. A wide variety of highly-substituted indenols are regiospecifically synthesized by this method.

Experimental Section

General. NMR spectra were recorded by a Varian Mercury-vx400 (^1H at 400.44 MHz and ^{13}C at 100.69 MHz), or Varian 400-MR Auto Tune X5 (^{11}B at 128 MHz) spectrometers. Unless otherwise noted, CDCl_3 was used as a solvent. Chemical Shifts were recorded in δ ppm referenced to a residual CDCl_3 ($\delta = 7.26$ for ^1H , $\delta = 77.0$ for ^{13}C), CD_3CN ($\delta = 1.94$ for ^1H , $\delta = 1.32$ for ^{13}C), and $\text{BF}_3 \cdot \text{OEt}_2$ ($\delta = 0.00$ for ^{11}B). IR measurements were performed by a FTIR SHIMADZU DR-8000 spectrometer fitted with a Pike Technologies MIRacle Single Reflection ATR adapter. High-resolution mass spectra were recorded by a Thermo Scientific Exactive (ESI) spectrometer. Column chromatography was performed with silica gel 60N (Kanto). Preparative thin-layer chromatography (PTLC) was performed on silica gel plates with PF_{254} indicator (Merck).

Materials. Unless otherwise noted, all chemicals and anhydrous solvents were obtained from commercial suppliers and used as received. Toluene was dried over Na-benzophenone ketyl. Ar-9-BBN¹², $(\text{DPEPhos})[\text{Pd}(\pi\text{-allyl})\text{Cl}]$ ¹³, and alkynylborate¹⁴ were prepared by according to literature procedure.

Preparation of Alkynylborates 1a: A Typical Procedure for the Preparation of Alkynylborates 1a,1b,1d-1f

To a stirred solution of *p*-ethynylanisole (1.45 g, 11.0 mmol) in THF (20.0 mL) at $-78\text{ }^{\circ}\text{C}$ was added *n*-BuLi (1.6 M in hexane, 6.9 mL, 11.0 mmol). After 30 minutes at this temperature, Ph-9-BBN (1.98 g, 10.0 mmol) was added and the cooling bath was removed. After being stirred for 1 h at room temperature, the reaction was quenched by adding a small amount of methanol. Then, volatile materials were removed under reduced pressure. The residue was dissolved in methanol and tetramethylammonium chloride (1.21 g, 11.0 mmol) was added with stirring at room temperature, resulting in white precipitates. It was collected by filtration and washed with cold methanol to give alkynylborate **1a** (2.7 g, 6.7 mmol, 67% yield).

Preparation of Alkynylborates **1c**.

Under an argon atmosphere, a solution of 3,3-dimethyl-1-butyne (0.84 g, 10 mmol) in THF (15 mL) was added to (H-9-BBN)₂ (1.22 g, 5.0 mmol), and then the mixture was stirred for 1 h at room temperature. In another flask, *n*BuLi (1.56 M in hexane, 7.3 mL, 11.4 mmol) was added dropwise to a solution of 4-phenylbut-1-yne (1.30 g, 10.0 mmol) in THF (15 mL) at -78 °C. After stirred for 30 minutes at this temperature, the two solutions were combined and then the cooling bath was removed. After being stirred for 1 h at room temperature, the reaction was quenched by adding a small amount of methanol. Then, volatile materials were removed under reduced pressure. The residue was dissolved in methanol and tetramethylammonium chloride (1.21 g, 11.0 mmol) was added with stirring at room temperature. After being concentrated under reduced pressure, the residue was dissolved in methanol again and stirred at -78 °C, resulting in white precipitates. It was collected by filtration and washed with cold methanol to give alkynylborate **1c** (760 mg, 2.0 mmol, 20 % yield).

¹H NMR (CD₃CN): δ = 0.38 (bs, 2H), 0.96 (s, 9H), 1.36-1.56 (m, 6H), 1.73-2.04 (m, 4H), 2.22-2.35 (m, 2H), 3.06 (s, 12H), 5.52 (d, *J* = 17.2 Hz, 1H), 5.91 (d, *J* = 17.6 Hz, 1H), 6.91 (dd, *J* = 5.2, 1.2 Hz, 1H), 6.98 (dd, *J* = 2.8, 1.2 Hz, 1H), 7.22 (dd, *J* = 2.8, 5.0 Hz, 1H); ¹³C NMR (CD₃CN): δ = 27.3, 27.6, 27.8-29.6 (m), 31.1, 32.7, 34.1, 35.2, 56.1, 90.8, 122.8, 125.1, 129.8, 131.4, 141.1. The boron-bound sp² and sp carbons were not detected due to quadrupolar relaxation; ¹¹B NMR (CD₃CN): δ = -18.1; HRMS (ESI) Calcd for C₂₀H₂₈BS [M-(NMe₄)]⁻ 311.2010. Found 311.2016.

Palladium/DPEPhos-Catalyzed Reaction of Alkynylborate **1a** with *o*-Iodoacetophenone (**2a**)

Under an argon atmosphere, a toluene solution (1.0 mL) of alkynylborate **1a** (80.68 mg, 0.20 mmol), dpephos)PdCl(π -allyl) (1.44 mg, 0.002 mmol), and *o*-iodoacetophenone (**2a**) was stirred for 1 h at 50 °C. To the reaction mixture were added aqueous H₂O₂ (0.5 mL, 30 wt%), aqueous NaOH (0.5 mL, 20 wt%), and MeOH (0.5 mL) at 0 °C. After being stirred for 2 h at room temperature, the resulting mixture was diluted with water and extracted with ethyl acetate (3×15 mL). The combined organic layers were washed by brine, dried over MgSO₄, and concentrated under reduced pressure. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 5/1) to afford the indenol **3a** (55.9 mg, 0.17 mmol, 85% yield).

The Synthesis of 2,3-Dialkylsubstituted Indenol **3m from 1-Octene, 4-Phenyl-1-butyne, and *o*-Iodoacetophenone (**2a**)**

Under an nitrogen atmosphere, a solution of 1-octene (145.9 mg, 1.30 mmol) in THF (2.0 mL) was added to (H-9-BBN)₂ (158.6 mg, 0.65 mmol), and then the mixture was stirred for 1 h at room temperature. In another flask, *n*-BuLi (0.69 mL, 1.6 M in hexane,

1.10 mmol) was added dropwise to a solution of 4-phenylbut-1-yne (143.2 mg, 1.10 mmol) in THF (2 mL) at -78 °C. After stirred for 30 minutes at this temperature, the two solutions were combined and then the cooling bath was removed. After being stirred for 1 h at room temperature, (dpephos)PdCl(π -allyl) (7.21 mg, 0.010 mmol) and a solution of o-iodoacetophenone (246.1 mg, 1.00 mmol) in toluene (2 mL) were added. The reaction mixture was stirred for 1 h at 50 °C. To the mixture were added aqueous H₂O₂ (1 mL, 30 wt%), aqueous NaOH (1 mL, 20 wt%), and MeOH (1 mL) at 0 °C. After being stirred for 2 h at room temperature, the resulting mixture was quenched by adding water and extracted with ethyl acetate (3×10 mL). The combined organic layers were washed by brine, dried over MgSO₄, and concentrated under reduced pressure. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 10/1) to afford the indenol **3m** (332.3 mg, 0.92 mmol, 92% yield).

IR (ATR): 3335, 1456, 1078, 752, 698 cm⁻¹; ¹H NMR: δ = 0.96 (t, J = 6.8 Hz, 3H), 1.29-1.56 (m, 15H), 1.60 (s, 1H), 2.08-2.27 (m, 2H), 2.74-2.81 (m, 2H), 2.87-2.94 (m, 2H), 7.19-7.28 (m, 5H), 7.29-7.36 (m, 3H), 7.42 (d, J = 7.2 Hz, 1H); ¹³C NMR: δ = 14.1, 22.6, 23.4, 24.7, 27.7, 29.3, 29.4, 29.5, 30.4, 31.9, 34.5, 82.5, 118.6, 121.3, 125.2, 126.0, 128.2, 128.3, 128.4, 135.1, 141.7, 142.5, 148.9, 149.4; HRMS (EI⁺) Calcd for C₂₆H₃₄O₄ [M]⁺ 362.2610. Found 362.2619.

IR (ATR): 3354, 1508, 1246, 764, 692 cm⁻¹; ¹H NMR: δ = 1.85 (bs, 1H), 3.86 (s, 3H), 5.67 (s, 1H), 6.92-6.97 (m, 2H), 7.18-7.38 (m, 10H), 7.63-7.66 (m, 1H); ¹³C NMR: δ = 55.2, 77.3, 114.3, 120.6, 123.7, 126.3, 126.8, 127.2, 128.3, 128.7, 129.2, 130.3, 134.2, 139.3, 143.2, 144.0, 144.3, 159.2; HRMS (APCI) Calcd for C₂₂H₁₇O₂ [M-H]⁻ 313.1234. Found 313.1237.

The ^1H , ^{13}C NMR and HRMS spectra were agreed with the reported value.¹⁵

Synthesis of indenone **4** and indene **5**

MnO_2 (170 mg, 2 mmol) was dried under vacuum for 5 h at 120 °C. Under an argon atmosphere, the solution of indenol **3n** (31.4 mg, 0.1 mmol) was added at room temperature. After being stirred for 3 h, the reaction mixture was filtered through a pad of celite, and concentrated under reduced pressure. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 10/1) to afford the indenone **4** (29.9 mg, 0.096 mmol, 96% yield).

The ^1H , ^{13}C NMR spectra were agreed with the reported value.¹⁶

Under an argon atmosphere, an ethylene glycol solution (1 mL) of indenone **4** (31.2 mg, 0.1 mmol), hydrazine (0.4 mL), and 2N KOH aq (10 μL , 0.02 mmol) was stirred for 5 h at 150 °C, and water was added. The aqueous layer was extracted with AcOEt (3 times), washed with water (once), brine (once), dried over MgSO_4 and concentrated under reduced pressure. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 4/1) to afford the indene **5** (17.6 mg, 0.059 mmol, 59% yield).

The ^1H , ^{13}C NMR spectra were agreed with the reported value.⁵

List of Publication

Chapter 1.

Solar-Driven Incorporation of Carbon Dioxide into α -Amino Ketones

Naoki Ishida, Yasuhiro Shimamoto, and Masahiro Murakami

Angew. Chem. Int. Ed., **2012**, *51*, 11750-11752

Chapter 2.

1,5-Rhodium Shift in Rearrangement of *N*-Arenesulfonylazetidin-3-ols into Benzosultams

Naoki Ishida, Yasuhiro Shimamoto, Takaaki Yano, Masahiro Murakami

J. Am. Chem. Soc., **2013**, *135*, 19103-19106

Chapter 3.

Stereoselective Synthesis of (*E*)-(Trisubstituted alkenyl)borinic Esters: Stereochemistry Reversed by Ligand in the Palladium-Catalyzed Reaction of Alkynylborates with Aryl Halides

Naoki Ishida, Yasuhiro Shimamoto, and Masahiro Murakami

Org. Lett., **2009**, *11*, 5434-5437

Chapter 4.

Iterative Approach to Oligo(arylenevinylene)s Containing Tetrasubstituted Vinylene Units

Naoki Ishida, Yasuhiro Shimamoto, and Masahiro Murakami

Org. Lett., **2010**, *12*, 3179-3181

Chapter 5.

Regioselective Construction of Indene Skeletons by Palladium-Catalyzed Annulation of Alkynylborates with *o*-Iodophenyl Ketones

Yasuhiro Shimamoto, Hanako Sunaba, Naoki Ishida, and Masahiro Murakami

Eur. J. Org. Chem., **2013**, 1421-1424

Other Publication

Construction of Indole Skeletons by Sequential Actions of Sunlight and Rhodium on α -Amino Acetophenones

Naoki Ishida, David Nečas, Yasuhiro Shimamoto, and Masahiro Murakami

Chem. Lett., **2013**, *42*, 1076
